Terry.

I have read some of the hybrid required test equipment posts. I will search and read up on it more today.

Today I use what I have and wish I had more. (I have used my guitar tuner as an AF signal generator for example.)

I worked on the TS-820 last night with my oscillospoce and my frequency counter, the Kenwood service manual, a DMM, and my new TS-820s notebook.

I slipped up on this project from the start. I didn't ask the universal repair question:

"OK. Who worked on this bucket last and what did they do?"
Last action: I added the CW filter.

After checking/adjusting a bunch of stuff, I still had to tune up with the CAR control cranked last night.

I moved the IF1 connector on the RF board to to position "A." Ta-da. No more CW filter in use and no more full clockwise CAR control requirement to get full output. Rig is back to "normal."

I got out the schematic and walked along the CW path so I knew what to try to test. There isn't much on that circuit to look at. My current guess? The used filter itself is at fault. I'll re-read Robert's testing the filter stuff in this thread. (Loved the "adjust with hammer" comment.) and the INRAD alignment instructions in the "files" section to learn more.

THE PLAN:

Read up on the INRAD alignment stuff in the files section.
Research bench gear for properly maintaining my hybrid.
I'll order up parts so I can work on the radio in June.

More news in June.
Thanks again, Stephen

>
> All of us had to start building test bench slowly over time. I and Mike and others have

posted many times on what is needed at a minimum to troubleshoot and maintain a Kenwood Hybrid and in what order to buy each piece. You dont need a lab grade RF bench, but something on order of Heathkit level is needed at a minimum. Sometimes there are alternate methods to accomplish the steps and other times you have to bite the bullet and realize the easiest and best method is to use the service manual prescribed test gear. There is no "only one way" but very often one way is clearly superior to others.
>
> Filters can be swept manually and the response shapes plotted on graph paper. I bit tedious but was done that way for years. I have notebook full of graphs before I got a decent sweep generator. Now I am lusting for VNA and/or Spectrum Analyzer and Tracking Generator. Even the old manual method requires a rf signal generator and a means to detect the RF output voltage at the frequency steps you inject.
>
> I dont know any way to measure the filter insertion loss without a means to measure the RF voltage at the input and at the output of the filter. Can use the rigs internal Carrier Osc signal, but still need a RF millivolt meter or an O-scope. No way around it.
>
> If you want to test the filter on the bench you can do that but you should terminate the input and output. I wont go into that test procedure here. Once you get correct gear I highly recommend you sweep any used filter on the bench before installing in rig.
>
> Absent a RF signal generator I think it is best for you to leave filter in the rig and use the Car Oscillator as your signal source. If you have a near by club might ask if someone will loan you an O-scope or RF millivolt meter or let you bring rig to their bench.

I bought a 830S yesterday & it came with a pair of New Taylor 6146B finals...
Past owner paid $47.00 each plus $10.85 shipping...
Thought I would offer them to the hybrid group before I post on QTH...
Would sell the pair for $80.00 plus $8.00 to mail...
Would use First Class Package with $100 of insurance...
They are New, never installed...
Will include RF Parts Co's invoice...
I also have a new GE 12BY7A driver, has the new box (from RF Parts)...
Would sell it for $20.00 (RF Parts sold for $22.95)
Thanks,
Bob

Bob,
They are only $23.00 each from RF Parts. $46.00 per pair!
That guy paid WAY too much for them.

I have a nice audio generator and it is required for some of the alignment, but today I doubt I would buy one. As you used your guitar tuner for audio lots of ways to get accurate audio signal tones and levels today with a lap-top pc and sound card and wide range of tone generator soft ware (some free) available to us.

Yes not likely that switching diodes or bias to turn them on was the problem but needed to check the entire change you made.

O-scope would have shown you filter input and output signals so pretty easy to tell that filter was causing high level of insertion loss requiring higher level of Carrier Oscillator output from Balanced Modulator.

We all take a chance when we buy used part either off internet or hamfesting. Use to be a little more integrity. Very different times.

Take Care
Terry K9TW

Rob:

If you are lucky all they did was change the Het Osc xtal for the 28 mhz bandswitch position. Do the other 10 meter bandswitch positions still work on 10 meters? If so, then most likely thing to look for is Crystal X7 33.5 mhz on the PD board was replaced with a 32.5 mhz crystal. Can buy a new replacement from International Crystal.
You may have to do re-alignment after replacing the crystal.

I would also do a visual inspection of the PA cage and rectifier board. Sometimes these fellows also QRO or badly abuse the rig. There are several things they can do for QRO, but most common is to move 300 to 210A or PD2 to increase screen grid voltage. Sometimes they short out R6 470 ohm on Rect Board with a jumper wire or install a 47 ohm in its place.

Take a good look at the main plate choke L3 in the PA cage to make sure not darkened (sometimes burned black). Also look at small right angle choke L1 at base of main choke for discoloration and look at the bypass cap C2. I have seen it burned and split open.

Make sure rig is unplugged and HV filter caps discharged before you poke around inside the PA cage or Rectifier Board.

Buenos Diaz Roberto,

Sorry to hear that you have the CB hack. I have had several pass over my bench over the past 2 years. I am NOT a professional repair person...just a hobby. I thing more than likely that crystals 9 & 10 on the VCO board have been changed. I up-loaded some pictures showing what I found on another 820(S): go to the FILES section of this board....then PHOTOS...look for TS820(S) CB HACK VCO MOD by wb7uqu.

Also, I agree with Terry. Compare wiring from the power transformer to the HV & rectifier board...as Terry stated..mods are easily done to QRO, just by moving a wire from one post to another...increasing the voltage to the final tubes...excessive voltage...running rig out of efficient operating parameters...will over heat the plate choke...and other components in the final cage...not to mention the HV and/or rectifier board...result...very sick...or dead rig.....

SALUD!

73 Joe

42231. New to the group. Repairing a 520SE. Rectifier board.

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-25 00:34:13 UTC
From: Wes Will
Topic: 42231 Message: 42231

Per the big schematic file, it's the "X43-1090-02" board, and the one that arrived in my shack was absolutely crispy. Purchased it "working" from a supposed friend, and when it got to my door it was no longer working; he was no longer my friend when I told him about it.

Long story short, I've got a bit of a rebuild job on my hands now. The DG-5 that came with it is in fine shape, likewise the nice Shure desk mike, all copacetic. Just the radio that won't work. Sigh.

(Limited budget, retired, ex-military, all that load of hu-hu. Spent all the savings I had earmarked for ham gear to get this rig, and now the boat doesn't mote, and the XYL is looking at me in "THAT" way for spending the cash. Oh well... C'est la vie, eh?)

Anyway, if anyone knows of a source for a replacement board that is in reasonable condition (or isn't in as bad a shape as this one in my hand - which wouldn't be hard - foil lifted off the phenolic, where it isn't just black char, popped capacitors, diodes cracked in half, etc.) I would be obliged. Otherwise I am going to have to etch and drill and populate a new one, by hand and it has been a long time since I've done any of that kind of work.

I -have- found a really great way to get the etch design onto the blank board, using my old LJ-4 printer and a clothes iron. But that's only the beginning. (I know the over-voltage probably damaged other things, but I have to have juice to the rest of the box to find them. A new rectifier board has to be the opening salvo in this war.)

Besides, if I have to make a new one I'm likely to redesign the sucker, putting in some filtering in the 14VDC line and such for one thing. Cleaning up the 120Hz pulsating DC that comes out of there HAS to help with the rest of the system, might even improve the receiver noise figures a bit.

So if there is any place to get a pulled rectifier board, I'd be much obliged to know about it.

Also, before I dive into the archives at random, would there be a specific place to look for a FULL-COLOUR photo, showing THAT rectifier board in sufficient detail to be certain of the wire colour that is on all of the various connections?

I want to be VERY sure when I hook this sucker back up, scavenged board or new-made one, that all the wires are in the correct place. Call me lazy, and don't want to have to follow EVERY one of the dozen and a half connections to this board BACK to the other end to make sure.

I will do so if there is no other recourse, and yes, I did make notes of what was where before I pulled the thing out of the chassis. I am a "belt AND suspenders" type, particularly when mucking about with 800VDC from a diode doubler circuit. That stuff can bite hard.

Anyhow, thanks in advance, and see you all on the radio. Once I get it fixed.

I have the complete X50--1340-00 PD board with all of the correct blue jacket crystals...
Also have the VCO bd. X50-1330-00...
I normally sell both of these boards inside the metal box for $75 plus mailing cost...

I have checked the transformer, both ohmed it out and powered it up to check the actual output voltages. Well within spec, all coils.

the 1090-00 would be just fine, or the one from the SE chassis, I'm easy.

"Pricing is low" is a good thing. OK, -how- low? The sooner I get this thing operational the sooner the evil eye gets turned down a notch.

I'll make one out of bark and twigs before I get taken to the cleaners, but if there is really a board for a reasonable price to be had, well, call me sold.

Also, how much for the SE chassis? I haven't any idea what the surge did to the rest of this poor thing, so I'd like a fall-back position in case there are other things needing repair.

Thanks for the reply.

I sell the Rectifier boards for $22.00 but just $18.00 here on the Hybrid board... Add $3.00 to mail to you...

I would have to find the 520SE chassis & see what's still on it...
I'll get back to you on that on Saturday...

Terry: I have a discolored L1 choke as you described below.Continuity checks OK but can't tell if its shorted.Cap seems ok. This monster will get hot as heck if I turn SG on.The foil side looks like it has been hot, the big resistors are dark colored but ohm out all right. Any way to check the L1 choke without getting the soldering gun out? Thanks for all the info, I'm brand new into component levels and just got a Tectronics 2213. Sad to say my Tripplet VOM has seen better days so looking for something to take it's place. jim

Rob:

If you are lucky all they did was change the Het Osc xtal for the 28 mhz bandswitch position. Do the other 10 meter bandswitch positions still work on 10 meters? If so, then most likely thing to look for is Crystal X7 33.5 mhz on the PD board was replaced with a 32.5 mhz crystal. Can buy a new replacement from International Crystal.
You may have to do re-alignment after replacing the crystal.

I would also do a visual inspection of the PA cage and rectifier board. Sometimes these fellows also QRO or badly abuse the rig. There are several things they can do for QRO, but most common is to move 300 to 210A or PD2 to increase screen grid voltage. Sometimes they short out R6 470 ohm on Rect Board with a jumper wire or install a 47 ohm in its place.

Take a good look at the main plate choke L3 in the PA cage to make sure not darkened (sometimes burned black). Also look at small right angle choke L1 at base of main choke for discoloration and look at the bypass cap C2. I have seen it burned and split open.

Make sure rig is unplugged and HV filter caps discharged before you poke around inside the PA cage or Rectifier Board.

Jim: Continuity as you know doesnt tell you much about L1 or any choke. Need inductance bridge to measure it. In the 520s thru 820s it is approx 3.0uhy. In the 530 and 830 it was increased to 6.8uhy.

Is the value critical? I would not go much above 6.8uhy. I have seen some with 4.7uhy installed. It is there primarily for VHF parasitic suppression, but it also facilitates 160 meter operation by supplying additional inductance for adequate Xl on 160 meters. That is why it is in series and at a right angle to reduce mutual coupling with main choke winding. It is very difficult to make an effective solenoid wound choke to cover the wide frequency range without having series holes fall into ham bands. So instead of using space windings on the big choke and adding this additional inductance value that would have made it too tall physically for the PA cage Kenwood added the small choke at the base.

My advice is to buy a PA cage rebuild kit from K4EAA or HybridRestore.
Good idea to replace the bypass cap even if it doesnt appear to be physically damaged. Has had lots of hours of use and is in pretty severe duty application.

What do you mean gets HOT with SG on? Are you talking heat from the 6146 finals? If so, what is the resting plate current doing? If rig isnt keyed should be no plate current or additional heat anywhere when you turn on the SG switch.

Also, what board has discolored foil side and dark colored BIG resistors? Are you talking about the Final Board with the two 10 ohm Brwn-Blk-Blk Cathode meter shunt resistors? If so, I would replace these resistors if they appear overheated. You can measure across them and should be approx 5.0 ohms but common to read approx 5.5 ohms or so. If much higher than that I would replace them. The two sources I mentioned above sell a kit for couple of bucks that has the cathode and screen grid resistors. Mouser and many other suppliers also sell resistors.

Of course with your VOM broken you will need to buy a meter. If I was to buy only one meter it would be a old Heath VTVM analog like a IM-11 or IM-18. If can afford two meters then get a low cost DMM for dc voltage and resistance measurements and the VTVM for rf and alignment work.

42239. Re: Progress report new 520SE acquisition

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-25 16:46:19 UTC
From: adrian.langford@ymail.com
Topic: 42105 Message: 42239

Well I've spent a happy hour probing my 520SE to measure the readings you suggested taking to diagnose my "no ALC on 10m". I can see why I'm not getting any ALC...

- On 28MHz I get no ALC, and only 5W indicated on external power meter when I tune the Plate and Load for max output.

- Loaded on 28MHz using peak receive noise, I have -84.5vdc cutoff bias in RX at pin 5 control grid

- In TX mode I have -53.2vdc operating bias

- RF drive voltage (measured with Tektronix 50MHz scope)is 36.0 peak rf volts

So using your workings I have 36-53.2 = -17.2V delta in TX mode, whereas I need a decent positive delta!

Please advise on next place to look for why the rf volts are too low (you were getting 60.8V peak rf compared with my 36V).

I haven't done any alignment yet as I'm waiting for correct tool to arrive, and don't want to crack any slugs through impatience.

Oh while I had the rig open I looked in the finals cage. Was interested to see the original Japanese valves had been replaced at some stage by 6146Ws.

73s from Adrian G4IQW

--- In TS-520_820_530_830@yahoogroups.com, "Terry Wagoner" <wagstw46@...> wrote:

> 2. ALC indication is full scale deflection(FSD)ie the needle is far right at "350 ma" with Car Level Pot at position "8" and Drive Control peaked at 1230.
> 3. DC bias voltage at 6146 control grid Pin 5 = -85.6vdc cutoff bias in RX mode and -51.4 vdc operating bias in TX mode.
> 4. RF drive voltage at 6146 control grid Pin 5 = 43.0 rms volts measured with a Boonton 92E RF millivolt meter.
>
> 43 x 1.414 = 60.8 peak rf volts
> 60.8 - 51.4 vdc bias = 9.4 volts difference. This is reason why I have FSD ALC indication. It is normal to require more Car Level voltage on 10 meters. If unsure just set it Full CW to start with.
>
> -51.4/1.414 = 36.0 rf volts. You must have greater than 36.0 rf volts at -51.4vdc operating bias to get any ALC indication. The Rf drive signal must make the 6146 control grid positive with respect to the cathode so that ua grid current flows to produce any ALC

indication. The greater the delta between dc bias and RF drive voltage on positive swing of the RF envelope the higher the ALC deflection will be.
>
> So you need to load your rig on 10 meters into dummy load. Since you have no ALC indication use a workaround like peaking the Drive Control on receiver back ground noise or use the Marker. After loading to full load flip the SG switch off and make the RF drive and DC bias voltage measurements on the 6146 control grid as I did above.

I would also be very careful citing and observing any of these "service bulletins". I am very skeptical of most of these as some are just flat wrong. Putting star lock washers on circuit board to cure VFO drift isnt first thing I will ever reach for! They appear to me to be nothing more than a list of one line anecdotal entries submitted by owners and perhaps Kenwood service center bench techs? One line entries with no details, no basis, no explanations are not what I would expect from a factory authorized service bulletin.
> > > >
> > > > I have worked on probably 30 or so TS520s in a 10 year period. Not an exhaustive number, but enough to know that all but one left my bench with adequate ALC indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.
> > > >
> > > > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> > > >
> > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > >
> > > > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.
> > > >
> > > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with

the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
> > > >
> > > > There is a reason that you may have no ALC indication in CW Mode at 200 ma Ip and it has to do with degenerative RF feedback, but I wont go into it in this response.
> > > >
> > > > Sorry so long, but this is not easy subject to cover briefly.
> > > >
> > > > If you want to work on your no ALC indication on 10 meters start with a fresh 12BY7A and make sure you have spec DC voltages and make sure your cathode resistors are all at design value.
> > > >
> > > > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.
> > > >
> > > > Not just my experience. You might contact Jimmy Lamanteer WB2KNR who still operates his original dealer purchased new TS520 as his main rig and collects them and has 8 or 10 at all times and he reports to me that they all have some level of ALC indication on 10 meters.

I meant to add that to see any ALC, I need rf volts greater than 53.2/1.414=37.6V, so my 36V peak doesn't cut it!

That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.
> > > > >
> > > > > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> > > > >
> > > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > > >

Would customers really live with that and call it normal? I dont think so.
> > > > >
> > > > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
> > > > >

> > > > >
> > > > > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.

Just remember a 50mhz BW scope on 28 mhz will read P-P voltage approx 8% to 9% low.

As far as where to go next. Well with your scope you can measure all the key TX Level Diagram test points for RF drive. Just multiply the Rms values listed by 2.828 for P-P that your scope will display.

Probably easiest is to take a look at Transmit Mixer output at the MD terminal or I believe you also have a TP-1 on the RF board. Should see something close to 2 rms volts or 6 volts P-P. If low there take a look at your Het Osc input. Het Osc serves as the LO for the Mixer and TIF as the RF input. TIF seldom problem but it could be. Output at MD is the actual transmit frequency which will be Het minus TIF. Should have about 1 volt of Het at TP-3. If low try adjusting the Het Osc coil. Make sure you peak it on slow side of the response curve and back off a little.

Terry K9TW

If you have good RF drive at output of the Transmit Mixer then look at the output at the Plate of the Driver Tube @DP on RF board. Just be aware you have 300 vdc here. Make sure you Scope probe and vertical amp can handle that level DC. Should have approx 160 v P-P.

Sometimes you may have to re-peak the Drive control depending on what instrument you are using to measure RF drive levels with as it can de-tune the tank circuits and cause a lower reading.

To keep from long responses I will wait to tell you where to look next based on your findings at MD and DP.

Terry K9TW

Thanks Terry for pointers. I will work way back and study level diagram alongside your instructions.

Oh I also tried to improve the VFO tracking but even going backband forth many times I couldn't get it really accurate at both ends 0 and 600. It's a slight improvement on how it was tracking before, and if Inuse calibrator again at 600 end then it's spot on. Without recalibrating against marker I can get it to 5.5000 at 0 end and 4.9004 at 600 end which will do for me.

I would also be very careful citing and observing any of these "service bulletins". I am very skeptical of most of these as some are just flat wrong. Putting star lock washers on circuit board to cure VFO drift isnt first thing I will ever reach for! They appear to me to be nothing more than a list of one line anecdotal entries submitted by owners and perhaps Kenwood service center bench techs? One line entries with no details, no basis, no explanations are not what I would expect from a factory authorized service bulletin.
> > > > > >

> > > > > > I have worked on probably 30 or so TS520s in a 10 year period. Not an exhaustive number, but enough to know that all but one left my bench with adequate ALC indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.
> > > > > >
> > > > > > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> > > > > >
> > > > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > > > >
> > > > > > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.
> > > > > >
> > > > > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
> > > > > >
> > > > > > There is a reason that you may have no ALC indication in CW Mode at 200 ma Ip and it has to do with degenerative RF feedback, but I wont go into it in this response.

> > > > > >
> > > > > > If you want to work on your no ALC indication on 10 meters start with a fresh 12BY7A and make sure you have spec DC voltages and make sure your cathode resistors are all at design value.
> > > > > >
> > > > > > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.

Subject: [TS-520_820_530_830] Re: Progress report new 520SE acquisition

I meant to add that to see any ALC, I need rf volts greater than 53.2/1.414=37.6V, so my 36V peak doesn't cut it!

> Any way
> to check the L1 choke without getting the soldering gun out?

Nope. Sorry. You cannot test the coil (or most any other part) without removing it from the circuit. At least one lead of any coil, capacitor, resistor, diode, or any other 2-lead device has to be out of the circuit to check it.

And use a soldering pencil and not a gun. About 35 to 50 watts should do just fine. Soldering guns are always much too hot for circuit boards. You'll melt the traces right off the phenolic.

You don't need to spend a load of cash to get something like a Weller temp-controlled soldering / desoldering station.

Now if money isn't an object, GET a Weller temperature-controlled soldering and desoldering station with the vacuum pump and all the fixings. (Sadly for me, I live on a retiree's tight budget, and money IS an object.) A decent pencil iron with replaceable tips should last for years, for -well- under thirty dollars.

Get a teflon-tipped solder-sucker bulb, too. Works better than solder-wick braid, for removing soldered-in components.

> Tectronics 2213. Sad to say my Tripplet VOM has seen better days so
> looking for something to take it's place. jim

Any of the Fluke DVM's are highly recommended. BEST is the industrial model 87V, but we're usually talking serious coin for one of them, in the $400 and up range. But a model 113 or 114 will do everything you will need when repairing a radio and costs a fourth of the price of the 87V.

The Fluke will last you the rest of your life. Put it in your will, it will still be going when you're gone silent key.

Or get an off-brand one that looks a lot like a Fluke, and will probably last you three or four years at least for $40 or $50.

Haunt places that have old gear for sale, if you've got any in your area, and find a VTVM instead of a digital multimeter, if you're going to work on tube stuff very much. The swing needle meters are quite good, and you can get very good at reading one quite soon. High input impedance, and they can be repaired by the owner, where a digital one cannot.

A Simpson 303 or something old by BK Precision (a model 177 for choice, were it me) won't do you wrong. And you'll probably be able to leave IT

to someone in your will, too. If they don't get dropped or dunked in something, they tend to just keep on truckin'.

(ALL METERS need to be checked for calibration once in awhile, against a standard known voltage source. Don't let anyone tell you otherwise, digital meters can get out of kilter too. But a VTVM, being a 'ball-park' sort of meter anyway, can be re-calibrated to 'close enough' at home, without sending it back to the factory for the job.)

Hope you get your rig un-modified without too much angst.

That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2

scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.
> > > > > >
> > > > > > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication
> on all bands I will take it. He was fuming by time conversation ended.
> > > > > >
> > > > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > > > >
> > > > > > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.
> > > > > >
> > > > > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I
> dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
> > > > > >

> > > > > > If you want to work on your no ALC indication on 10 meters start with a fresh 12BY7A and make sure you have spec DC voltages and make sure your cathode resistors are all at design value.
> > > > > >

> > > > > > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.
> > > > > >

Thanks Jerry. I do have a pair of new RCA 6146Bs as spare, but the 6146W are putting out 100+ W on all bands except 10m where I have no alc indication

I am looking on ebay for an antenna tuner for this radio and have found various older kenwood tuners. Will the at-230 work with the 520SE?

I use the Dentron Supper Tuner, large knobs & easy to tune... :)
You can pick one up for around $125

Topic: 42105 Message: 42250

Hi Terry,

Thanks for all your help with this! I took all the readings below loaded for 28MHz, and with SG switch off but a dummy load attached.

At MD I got 6.4V p-to-p. By the way the waveform looked very "messy" here (fuzzy, badly defined peaks, like lots of faint AC waves superposed on each other), though it's very clean at the pin 5 Control Grid. Is that normal?

At DP I got a lot less than 160V p-p, measured 66V p-p then tried re-peaking the drive and could get it to 80V p-p, still way below your value and the 49V rms shown on the TX level diagram.

TP3 showed 1.4V p-p.

So I'm puzzled by a) the messy waveforms and b) the low DP reading. I dropped in a new 12BY7A just the other day and am getting 100W on other bands. What else can take DP low?

I haven't tried adjusting the Het Osc coil as I won't have the correct tool for a few days.

At least I am learning my way round the various test points! It's superbly arranged for DIY maintenance.

The AT-230 will be fine. I use an AT-130 (only one antenna input and just a cheap level type meter for dipping the controls, and no built-in dummy load. But it can handle the power and like all Kenwood stuff of this vintage is superbly built.

Correction the Het Osc on 28MHz was 2.5V p-p

Interestingly on 21MHz and 14MHz the Het Osc output was higher at 3.5V p-p.

I use no antenna tuner, if the swr is within 3 to 1, the radio serves as
a built in antenna tuner if you follow
the radio's tuning instructions.
Been working this way for years without a problem.
The only thing a tuner does is fake out the radio anyway to make it
think it's getting good swr and not blow the finals.

Just my 2 cents worth...let's see, if you factor in inflation that would
be what? two dollars???

Adrian: You are doing well. I enjoy helping someone who is able to take some basic readings.

First of all 6146W finals are just fine for any hybrid. I run them all the time. They neutralize fine. When I cannot get 6146Bs my 2nd choice is Sylvania (JAN) 6146Ws from RF Parts. I have a pair in my TS-830 right now and easily get 100 watts out on all bands.

OK MD level is good at 6.4v P-P. Normally TIF is dirty (harmonic rich) due to Het or VCO leak back. MD is as I mentioned the actual transmit output frequency and it may be a little dirty (some 2nd harmonic), but not anything like TIF signal unless there is a problem with your TX Mixer. Scope can have problem syncing on TIF. Take a look at it for interest. I have covers on my 520 now, but may take them off and take a look at MD but pretty sure not normally harmonic rich.

Kenwood went to the Doubly Balanced Mixer config (uses two Mosfets) with the introduction of the 820 and retained it in the 530 and 830. This is superior mixer config as has very little to no Carrier or TIF signal present in the output. The 530s and 830s have a balance pot to ensure you can null the 2nd harmonic content (17.660 mhz).

Het Osc level is a little low but not bad. Might want to tweak it when you get your tuning tool. Het board hangs below the rf board on bottom side of your rig. It is the first board nearest front panel and you can see a picture of it in your owners manual and the 28 mhz coil.

The low rf drive level at DP is not a good sign. Especially given that you have a fresh 12BY7A and it works good on 14 and 21 mhz bands. This tells you that all the tube DC voltages are to spec. The important ones are the operating bias on control grid (just slightly positive) and the SG voltage when flipped to Send. These voltages have to be good, but you can measure them if you want. They are not band specific so if good on 14 and 21 then have to be there for 10 meters.

If you are telling me that you have no ALC indication and very low RF output on 10 meters it smells like bandswitch problem to me. The Driver tube plate must see a tuned circuit that is switched in. Absent that parallel resonant tuned circuit the rf voltage will be low.

On 10 meters no fixed capacitor is across the 10 meter Drive coil. They use the tubes inter-electrode capacitance and the parasitic capacitance of the foil traces and band switch traces to tune that coil to resonance.

Most likely problem is that you either have bad 10 meter drive coil or bad 10 meter band switch position. I have never seen a bad coil unless it was a physically damaged one. Hopefully it is just a severely mis-tuned 10 meter drive coil?

Subject: [TS-520_820_530_830] Re: TS820 MODDED

Jim: Continuity as you know doesnt tell you much about L1 or any choke. Need inductance bridge to measure it. In the 520s thru 820s it is approx 3.0uhy. In the 530 and 830 it was increased to 6.8uhy.

Is the value critical? I would not go much above 6.8uhy. I have seen some with 4.7uhy installed. It is there primarily for VHF parasitic suppression, but it also facilitates 160 meter operation by supplying additional inductance for adequate Xl on 160 meters. That is why it is in series and at a right angle to reduce mutual coupling with main choke winding. It is very difficult to make an effective solenoid wound choke to cover the wide frequency range without having series holes fall into ham bands. So instead of using space windings on the big choke and adding this additional inductance value that would have made it too tall physically for the PA cage Kenwood added the small choke at the base.

My advice is to buy a PA cage rebuild kit from K4EAA or HybridRestore.
Good idea to replace the bypass cap even if it doesnt appear to be physically damaged. Has had lots of hours of use and is in pretty severe duty application.

What do you mean gets HOT with SG on? Are you talking heat from the 6146 finals? If so, what is the resting plate current doing? If rig isnt keyed should be no plate current or additional heat anywhere when you turn on the SG switch.

Also, what board has discolored foil side and dark colored BIG resistors? Are you talking about the Final Board with the two 10 ohm Brwn-Blk-Blk Cathode meter shunt resistors? If so, I would replace these resistors if they appear overheated. You can measure across them and should be approx 5.0 ohms but common to read approx 5.5 ohms or so. If much higher than that I would replace them. The two sources I mentioned above sell a kit for couple of bucks that has the cathode and screen grid resistors. Mouser and many other suppliers also sell resistors.

Of course with your VOM broken you will need to buy a meter. If I was to buy only one meter it would be a old Heath VTVM analog like a IM-11 or IM-18. If can afford two meters then get a low cost DMM for dc voltage and resistance measurements and the VTVM for rf and alignment work.

Terry, when I get the rectifier board back in this thing (one is now on order, thanks to Bob, KE5FTF) do you mind if I pick your brains like this? I'm SURE that the short in the high voltage lines had to cause something else to go south in this poor rig, and watching you talk Adrian through this was a lesson in itself.

(I had a thought near the beginning of the thread, about the band switch. Has it been checked over and thoroughly cleaned? Might be all that's needed to get 10M back up to snuff.)

I can assure you I'm an old hand at taking measurements and reading schematics, so I won't disappoint there. Knowing that there could be some assistance if needed would be great.

Could be that a pointer to the troubleshooting and test-point voltages will be enough. I take it that it is somewhere in the files for this list?

There is always the chance that there is nothing wrong with this thing, once it gets the juice it is expecting, but I'm not going to count on it.

Terry,

I just wanted to follow up on the Q&A below. I finally got a high quality dummy load and used it instead of the dummy load in the MFJ tuner. That seems to have corrected the problem. The erratic IP during tune up is gone.

When I measure the dummy load in the MFJ tuner, it’s 49 ohms, but as we all know, it’s one thing to pass a tiny amount of DC current through a carbon rod and quite another to pump 120 watts of RF thought it.

Thanks again for your help.

Louis

Yes I did not say anything about the external load coming and going.

Good idea to check dummy load and any coax jumpers PL-259 connectors from rig to dummy load (any cable/connection combination from rig to the dummy load). Do that before anything in the rig. On rare occasions the lead at the SO-239 inside the pa cage can have a poor solder connection. Also the Antenna T/R relay NO contacts could be dirty.

Should have told you to look at external load stuff first. Pulled the trigger too quick. Sorry about that.

For what it's worth, I checked the ESR of the large power supply capacitors and it was well under 1 ohm.
> >
> > But it has one problem that has developed recently. During initial tune-up after power on, the IP jumps around erratically while adjusting the plate control. It dips but it jerks around, not a smooth dip. It settles down and acts normal after a keying and adjusting the plate control several times, and then the rig tunes up fine. If I tune up again on the same band or a different band, it tunes up fine without acting erratic. But if go away and come back another day, the erratic IP during tune up comes back.

Should have told you to look at external load stuff first. Pulled the trigger too quick. Sorry about that.

hi Terry! I guess i wasnt asking my Q right/ ihave a ts520se/ and i understood the 6146 finals and the 6146a worked fine / but the 6146b and 6146w caused parisetic oscillations or cud not be neutralized or did i just misunderstand the article/ can i use a a,b or w in the finals that of course being the suffix

Terry, when I get the rectifier board back in this thing (one is now on order, thanks to Bob, KE5FTF) do you mind if I pick your brains like this? I'm SURE that the short in the high voltage lines had to cause something else to go south in this poor rig, and watching you talk Adrian through this was a lesson in itself.

(I had a thought near the beginning of the thread, about the band switch. Has it been checked over and thoroughly cleaned? Might be all that's needed to get 10M back up to snuff.)

I can assure you I'm an old hand at taking measurements and reading schematics, so I won't disappoint there. Knowing that there could be some assistance if needed would be great.

Could be that a pointer to the troubleshooting and test-point voltages will be enough. I take it that it is somewhere in the files for this list?

There is always the chance that there is nothing wrong with this thing, once it gets the juice it is expecting, but I'm not going to count on it.

Wes: My rigs are all starting to blur together. Trying to help too many folks at one time. When you are ready just come back and refresh all of us with what the original problem is or was and where you are at with it. One of us will be glad to help you. In addition to looking in the Files section you can use the Advanced Search and put key words in related to your question. It is not the best, but I try to do that before asking. Not too many questions that have not been answered before.

I have never seen a Hybrid with a plain 6146 in it. Some claim that the slight difference in the inter-electrode capacitance between the various 6146 tubes causes problems with neutralization or for neutralization not to "hold". K9STH has written extensively about this and is quite passionate about it. I have never seen a problem with it in a hybrid and I do not subscribe to neutralization drifting or not holding. If neutralization is drifting in a hybrid I would suspect a loose neutralization capacitor rather than the tube capacitance changing. Just have never seen it.

I think the orginal hybrids came with S2001 and S2001A tubes. I think the S2001A has more plate dissipation and are equivalent to a 6146B, but do not know for sure as I have never seen a S2001 or S2001A factory data sheet.

I do not believe that the slight difference in inter-electrode capacitance makes any difference at all. I would just not mix 6146 tubes with different suffixes.

Just my opinion and experience.

This has been covered here many times before.

>
> First of all 6146W finals are just fine for any hybrid. I run them all the time. They neutralize fine. When I cannot get 6146Bs my 2nd choice is Sylvania (JAN) 6146Ws from RF Parts. I have a pair in my TS-830 right now and easily get 100 watts out on all bands.
>
> OK MD level is good at 6.4v P-P. Normally TIF is dirty (harmonic rich) due to Het or VCO leak back. MD is as I mentioned the actual transmit output frequency and it may be a little dirty (some 2nd harmonic), but not anything like TIF signal unless there is a problem with

your TX Mixer. Scope can have problem syncing on TIF. Take a look at it for interest. I have covers on my 520 now, but may take them off and take a look at MD but pretty sure not normally harmonic rich.
>
> Kenwood went to the Doubly Balanced Mixer config (uses two Mosfets) with the introduction of the 820 and retained it in the 530 and 830. This is superior mixer config as has very little to no Carrier or TIF signal present in the output. The 530s and 830s have a balance pot to ensure you can null the 2nd harmonic content (17.660 mhz).
>
> Het Osc level is a little low but not bad. Might want to tweak it when you get your tuning tool. Het board hangs below the rf board on bottom side of your rig. It is the first board nearest front panel and you can see a picture of it in your owners manual and the 28 mhz coil.
>
> The low rf drive level at DP is not a good sign. Especially given that you have a fresh 12BY7A and it works good on 14 and 21 mhz bands. This tells you that all the tube DC voltages are to spec. The important ones are the operating bias on control grid (just slightly positive) and the SG voltage when flipped to Send. These voltages have to be good, but you can measure them if you want. They are not band specific so if good on 14 and 21 then have to be there for 10 meters.
>
> If you are telling me that you have no ALC indication and very low RF output on 10 meters it smells like bandswitch problem to me. The Driver tube plate must see a tuned circuit that is switched in. Absent that parallel resonant tuned circuit the rf voltage will be low.
>
> On 10 meters no fixed capacitor is across the 10 meter Drive coil. They use the tubes inter-electrode capacitance and the parasitic capacitance of the foil traces and band switch traces to tune that coil to resonance.
>
> Most likely problem is that you either have bad 10 meter drive coil or bad 10 meter band switch position. I have never seen a bad coil unless it was a physically damaged one. Hopefully it is just a severely mis-tuned 10 meter drive coil?

> I would just not mix 6146 tubes
> with different suffixes.

I don't know if it would make a lot of difference for these hybrid rigs, but back when I was learning this stuff, it was tubes and nothing but.

We would not only "not mix ,,, suffixes," but for almost any dual-tube amplifier set-up of any class or frequency (bass guitar amps to what passed for VHF back then), we would pull out the tube tester and start testing tubes in batches.

We'd number them, then test and write down the exact results of the tests. This was all done in order to get two that had most-nearly identical outputs and inter-electrode capacitances and internal resistance figures and anything else we could test for.

I doubt that it would help all that much for these hybrids, but it likely couldn't hurt, and might just get that last little bit of performance out of them. (Transmission clarity, stability, power, what-have-you.)

Just a thought, and kind of a remembrance of the end of the tube era.

Back then you were dealing with Audio and not RF. The configuration was Push-Pull and not Parallel. The objective of matched pairs for Push-Pull Audio Amplifiers was to ensure that each tube had equal plate current so you minimized crossover clipping or distortion.

There are those who insist on paying for 6146 tubes that test close to same transconductance in a tube tester. It amuses me and I would like to ask them how they reconcile not having separate bias controls and a meter switch to set the resting plate current exactly the same on each tube when they install them and as the tubes age. Absent that how to you ensure each shares half the load? I would not be too concerned about linearity if one tube has slightly higher idle current than the other. Even if one tube was shifted slightly toward AB2 the ALC comes in to play the moment there is any hint of grid current. In parallel operation there is no cross over point to be concerned with.

I suppose if you bought matched pairs and had a way to set idle current on each one you could ensure that each tube was sharing the load equally and might extend the life of one tube over the other, but doubt if any measurable difference.

Just my opinion.

42266. TS-520 Het Osc Measurements

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-26 12:14:13 UTC

Topic: 42266 Message: 42266

Adrian:

OK-You talked me in to taking off covers of my TS-520.

I looked at MD on scope (new Rigol DS1102E) and it is not clean sine wave on any band. It does not want to sync. It is not as dirty as TIF, but does have some harmonic content. My scope displays frequency as well as peak to peak voltage and when it does sync it displays 17 mhz for a moment so it has to be looking at 2x TIF signal. This surprises me a little as the HET osc injection level is significantly higher (as it should be)than the TIF signal level.

I also connected my good counter at MD and it has trouble locking on it and I get flashes of 17 mhz so it is also seeing 2x TIF.

As you note the rf signal at the 6146 control grids is a clean and stable sine wave. I checked MD on several bands and got same result.

Here are my Het signal levels at TP-3 with 100mhz scope and with Boonton 92E. You will note that the P-P levels do not match the RMS levels. I suspect this is due to the harmonic content the scope is measuring?

3.5 = 5.36 p-p = 1.60 rms
7.0 = 5.44 p-p = 1.62 rms
14.0 = 5.68 p-p = 1.68 rms
21.0 = 5.65 p-p = 1.67 rms
28.0 = 5.72 p-p = 1.70 rms
28.5 = 5.68 p-p = 1.68 rms
29.1 = 5.65 p-p = 1.67 rms

When you get your tuning tool suggest you adjust 10 meter Het Osc level to see if any improvement in DP level. I suspect not but easy first thing to do. After that try adjusting 10 meter Mixer and Drive coils.

Also, have you looked at the 5 watt 10 meter output into dummy load with your counter? Can use a small 2 or 3 turn sniffer coil connected to your counter test lead and placed near slots in PA cage. Are you seeing 28 mhz? Is your Tank capacitor (plate tuning) at its normal position for 10 meter loading?

I'm running 6146 W JAN's from GE and they work
fine. No issues with neutralization and I get
100+ watts output. I purchase them from RF Parts.

http://www.rfparts.com/6146w-ge.html

As I recall I'm running them in my TS-520S and my TS-830S.

Hi Mark:

Any Kenwood bargains at Dayton? Did Dick and his son make it? I hope to make it back next year. Terry

Yes, Dick and his son Jeff made it. He flew in
this year so was not expecting to pick anything big up.

Lots of bargains, but ended up only bring home
some Drake stuff. I'm still puzzled over the
number of Collins equipment, like the R390's,
75A4, etc. that was there. Seems there was an
unusually large amount of that stuff for what ever reason.

Hope to see you next year, or maybe Ft. Wayne. Do
you ever get down to the Findlay hamfest in the
fall? That's one that I always attend.

Mark

Yes I have flown in before in a Cessna 172 with 3 other hams so no way to lug those Johnson Viking IIs back!

Well glad you had good time.

I have not been to Findlay or Lima or Mansfield in many years. Use to make Findlay and set up and sell there. I will make a note about it and probably will make Ft. Wayne again. I think Findlay is about 2.5 hours from the house.

Take Care
Terry

Jerry,

Maybe you should take some time and read Tom Rauch's (W8JI) webpage on
amplifier stability.

http://w8ji.com/hf_stability.htm

and his page on VHF stability

http://w8ji.com/vhf_stability.htm

Hey cliff i know this out of group but have a ts-711a and its over heating and fan does not kick in at all ! checked fan and its good . do you know what i could do to fix problem ? could i wire fan direct? or do i have to find a relacement thermistor which is a TH1 (SDT1000F)which is discontinued or could you direct me some kind of replacement?

Thanks and 73s Kd5utc Rick Schofield

You could use a 'snap disc' switch which turns on at a selected temperature. Pexsupply.com has them at reasonable prices.

Hi Mike:

I have never seen a Kenwood Hybrid exhibit any type of parasitic oscillation VHF or near the fundamental. For that matter never saw any 6146 rigs have this problem. Maybe I wouldnt recognize it?

I have set the Pi-network load cap to approx 50% and keyed the rig with no drive and tuned the Plate Tune cap thru its range slowly and watched the Plate current meter and have never seen any meter movement. I have done this on all bands. This is a standard stability test.

I think the bigger worry with our Kenwoods is thermal runaway. This is far more likely to occur and has destroyed more 6146 finals than parasitics ever has.

I experienced this one time while trying to adjust the bias voltage pot to set the resting plate current. The pot had a bad spot in it and I lost operating bias voltage and the rig made a loud hum and rattling noise and the plate meter pegged and the finals glowed cherry red. This all happened in a micro-second and no way to catch it. Today I clean and exercise bias voltage pots with rig not powered and then make initial power on setting by measuring the bias voltage at control grid with SG switch off. After that I feel safe to set the resting plate current.

I suspect parasitic oscillation is possible otherwise Kenwood would not have placed suppressors in the anodes and grid leads. Although sometimes old time design just gets installed in later models as a precaution or it is just copied by designers as standard or good practice and the tube internal geometry and lead layout and propensity for parasitics may not have even been fully analyzed. No way to tell what Kenwood had in mind.

Take Care
Terry K9TW

Hi Terry,
I am up north visiting the grandsons and keeping up with the discussions. I noticed the discourse has again turned to the 6146 W argument. I have been using W's in a 530 with no ill effects observed, on the bench or on the air. K4EAA. has a very good explanation about using them. I refuse to throw good valves away. Anyhow I did not want to pollute the 520se post as it is progressing well. I cannot wait to see the next post. A lot of good information being exchanged. I did want to update my attenuator project just for record. I have read some good articles this past week and have ordered parts for a 2dB single. After I find how that works out, I will design a gang box unit to drop down into the QRP universe. I am active on 17 CWDX QRP but I want to start using my 830 w/extVFO instead of my homebrew tuna tins. More and more dxops using splits. Sorry for long post. 73, Don K5HFG

42276. KENWOOD HYBRID USER NET (May 26th, update)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-26 19:02:40 UTC
From: mvgilger
Topic: 42276 Message: 42276

There was no net last weekend due to Dayton Hamvention. For any that did not attend, it was a good hamvention with lots of used Kenwood equipment in the flea market. I think I saw maybe a half dozen TS-830's and 530's, and 3-4 820's. All seemed to be in nice condition.

The Saturday's net on 40 meter had 16 stations checking in with good band conditions. We had 8 new check-ins today, W3GD, W4TRJ, K1VOY, W4AKG, KC1BE, KA1SJD, K2KRP, K2IB. Out of all stations checking in, there was:

3 running TS-520(x)
1 running TS-530(x)
3 running TS-820(x)
0- running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 14 stations checking in under very poor band conditions. We had 9 new check-in, WO5O, N5YHC, KF4DYN, KJ4ZPB, WA6UVB, NR6C, and KI6IJI.

Out of those, there was:

2 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
4 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39
April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 45, Sunday's total = 50(Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Hi Don:

Hope you are enjoying visit with grandsons. Well there will be as many opinions as there are people and sometimes no amount of logic will prevail. Brand loyalty is a funny thing and rational thinking is not required. Just makes it hard for a new person to sort out the facts from the feelings and beliefs. Fortunately none of this is earth shattering in the grand scheme of life.

I was just hoping in my life time that Shuguang factory (makers of Taylor and Penta 6146 tubes) would figure out how to make a S2001A or RCA 6146B equivalent that would have long service life in Kenwood hybrid service. I dont think they are there yet and I wonder if anyone ever told them what operating voltages we run them at? Sure would be nice to buy a brand new 2013 manufactured set of 6146 finals that like 900vdc plus on the anode.

Be interested to hear how your pad attenuator works out.

Enjoy the holiday with the kids.

73s Terry K9TW

I took out some boards for cleaning, but did not realize not all male pins were used on this board, and now I'm not sure which ones to use. :-(
Click here to see the photo of the connector in question
<http://www.361euros.com/skitch/image-20130526-170951.jpg>
I plugged the 3-pin female connector in using the right most 3 pins (#1,2 & 3), leaving the 2 left ones (#4 & 5) unused, but I honestly don't know which 3 of the 5 male pins were used before I unplugged it, so I don't want to power up the machine just in case.
Any help will be GREATLY appreciated! :-)

You have it in the correct spot.
It goes on Pins 1,2, 3 there is nothing on pins 4 and 5

To Clarify, If you had the CW filter installed, you would move it over
one or two pins.
It tells about it towards the end of the user manual on page 34 of the
one I have.

No problem Jerry, I intended for this thread to identify some old issues and opinions about the 6146. I am currently using A,B and W's in various Hybrids. I have a tendancy to Not throw any valves away until they positively do not work.

Terry,

I did want to comment on your encounter with the runaway finals. I had this happen to me in two different rigs this past winter. I never work on a clean Hybrid.(except my personal rigs) I have gotten several on eBay as project rigs and also for the learning experience. Never concerned about there condition or where they come from. I use them as learning tools and then send them to whomever wants them. As long as I can break even or somewhere in that vacinity. If I know they do not function properly then I keep them here until they do. Anyway, I ran into the problem you describe after I had them working for a period of time. I had each one on the bench for a check out and the tubes ran away as soon as I flipped the send switch. Cherry red in a millisecond,condensors snapping,and sparks flying. A man can not react that fast. After shutdown and repair I cleaned the pots and exercised them and have not had a problem with them since. They are 530's and both have a permanent spot in the station. Working fine. I do not have a clue as to why they did that. I have been keeping an eye on them but they seem fine now. Just thought it was more than coincidence. Always thought that was something that happened to others. Now I always clean everything.....

This is another one of those questions that could have been easily answered IF the owner would had taken the time to read the operator's manual FIRST! Page 34, Figure 25 "Installing the CW Filter"clearly shows how to connect the plug you are referring to!

Terry (K9TW),

I cleaned the AUX relay and the antenna TR relay, though both of them looked very clean. I even swapped them too, but that did not solve the problem, so I will look into measuring the AGC bus voltage next and double checking the regulated voltage (9v).

If I'm not getting the 3v on the AGC, what would you suggest I look into next?

Thanks again! ;-)

> > >
> > > There are several places you can measure the AGC bus voltage. On the IF board at Conn IF-3 Pin 11 for example. You need at least a 10 to 11 meg ohm meter. Even that meter will pull the voltage down some. Should have approx 3 vdc with RF gain full CW. If lower or missing common to start by measuring at it source and cleaning Aux relay contacts that switch it.
> > >
> > > A short lesson....The RF and IF amplifiers in the radio are all dual gate mosfets. We call these "gain controlled" stages. We use a variable positive dc voltage (approx 3.5vdc) applied to Gate 2 of these devices to automatically control the gain of these devices. We

call this control voltage AGC. This 3.5 vdc control voltage is derived from the RF-1 voltage on the AF-AVR board. With approx 3.5vdc applied to the Gate 2 of these devices they have maximum gain and as the voltage is lowered the gain is lowered (assuming all other required dc voltages to the devices is to spec).
> > >
> > > Two things normally lower this control voltage....receiving a strong off air signal and you running RF gain pot back CCW. The S-meter simply monitors the AGC bus line and when it sees the voltage go down it moves the meter up scale. Also, If the AF-AVR board fails you will have no RF-1 to supply the AGC bus so that is why I suggested you also measure it.
> > >
> > >
> > > You have two identical relays in the radio. One is the Aux relay that controls functions like switching the AGC and ALC bus line voltage and the other is your Antenna TR relay. These are plug in relays and very easy to remove and clean. Pull the Aux relay and carefully remove the plastic cover and clean the NC and NO contacts by wetting strip of printer paper with Deoxit and placing between the contacts and applying gentle pressure to the movable armature and pull the paper thru. Should see black traces on the paper. Do this several times and then blow out relay with canned air.
> > >
> > > When you report you had good receive one moment and then the level went down or became nearly non-existent and the S-meter is now pegged it sounds like the AGC bus voltage available at the IF Board and RF board to be applied to Gate 2 of the IF and Rf amp devices is very low.
> > >
> > > So I still recommend you check RF-1 on the AVR board and make sure it is available and set per the service manual. First step in alignment is checking and setting the regulated 9vdc and the RF-1 voltages.
> > >
> > > Remove the bottom cover of the radio after line cord has been unplugged and rig allowed to sit for awhile to ensure filter caps have bled off. The Aux Relay is about in center of radio next to two vertically oriented filter capacitors about on a line back from the VFO knob. The Ant relay is under a metal shield can in rear corner. You can remove both and clean contacts. Some folks rotate the position of these relays from time to time to place them in different service. Kens Electronics in Kalamazoo Mich has NOS replacements. He has a website. Not a bad idea to have a spare.

Well. I see that this list is not as I had first thought immune to the
"RTFM" rant that seems to be so prevalent elsewhere.

Sad. I had such high hopes.

Wes,

I like most other people come to this forum to learn, teach and help each other. But if someone can't be bothered to read a manual first to try and understand the basics or attempt to understand their radio issue, it takes a lot of time to continually re-hash the same basic information. There has been numerous email attacks on the generous individuals that have the knowledge and ability to teach and help others. Saying that, if a person can't be bothered to take the time to read or download a manual and then to verbal someone for writing a lengthy email to help such individuals then this forum will suffer by losing the great individuals that give their time and knowledge freely. This does not include the people who ask where to download a good copy of the mauals, because they are at least trying! So please before taking the high road of "thought this forum was immune to RTMF", when making these statements you should consider just how much time people put into helping others and usually don't even receive a thanks once the information to repair their radio has been given. NOT that they are looking for thanks but just once in a while it is nice to get some acknowledgement instead of negativity. If a person can't read a manual on how to tune your radio when it is working how do you expect to teach someone to repair it. I have had one of these hams work with me on a radio for weeks just to repair the bloody thing, the only reason it took so long because it had someone with no knowledge or respect who stuffed it up in the first place.

Relay cleaning was simple first step.

Now Go to IF board Conn IF-3

1. With power off measure AGC bus resistance at Pin 11. Should be approx 1.7 meg ohm.

2. With power on measure RF-1 at Pin 8. Should be approx 3.4vdc

3. With power on and RF gain pot full CW measure AGC at Pin 11. Should be approx 2.8vdc with a 11 meg VTVM and somewhat less with a 10 meg ohm DMM.

4. If RF-1 is OK and AGC is very low you can try applying 3vdc to Pin 11 and see if rig comes alive. If you do not have a bench supply then use a Radio Shack battery holder and series up couple of 1.5vdc C or D cells. Connect negative lead to chassis ground and touch positive 3vdc lead to Pin 11. Rig should come alive. Watch S meter and see if it comes off the peg.

Report back your findings.

> > > > There are several places you can measure the AGC bus voltage. On the IF board at Conn IF-3 Pin 11 for example. You need at least a 10 to 11 meg ohm meter. Even that meter will pull the voltage down some. Should have approx 3 vdc with RF gain full CW. If lower or missing common to start by measuring at it source and cleaning Aux relay contacts that switch it.
> > > >
> > > > A short lesson....The RF and IF amplifiers in the radio are all dual gate mosfets. We call these "gain controlled" stages. We use a variable positive dc voltage (approx 3.5vdc) applied to Gate 2 of these devices to automatically control the gain of these devices. We call this control voltage AGC. This 3.5 vdc control voltage is derived from the RF-1 voltage on the AF-AVR board. With approx 3.5vdc applied to the Gate 2 of these devices they have maximum gain and as the voltage is lowered the gain is lowered (assuming all other required dc voltages to the devices is to spec).
> > > >
> > > > Two things normally lower this control voltage....receiving a strong off air signal and you running RF gain pot back CCW. The S-meter simply monitors the AGC bus line and when it sees the voltage go down it moves the meter up scale. Also, If the AF-AVR board fails you will have no RF-1 to supply the AGC bus so that is why I suggested you also measure it.
> > > >
> > > >
> > > > You have two identical relays in the radio. One is the Aux relay that controls functions like switching the AGC and ALC bus line voltage and the other is your Antenna TR relay. These are plug in relays and very easy to remove and clean. Pull the Aux relay and carefully remove the plastic cover and clean the NC and NO contacts by wetting strip of printer paper with Deoxit and placing between the contacts and applying gentle pressure to the movable armature and pull the paper thru. Should see black traces on the paper. Do this several times and then blow out relay with canned air.
> > > >
> > > > When you report you had good receive one moment and then the level went down or became nearly non-existent and the S-meter is now pegged it sounds like the AGC bus voltage available at the IF Board and RF board to be applied to Gate 2 of the IF and Rf amp devices is very low.
> > > >
> > > > So I still recommend you check RF-1 on the AVR board and make sure it is available

and set per the service manual. First step in alignment is checking and setting the regulated 9vdc and the RF-1 voltages.
> > > >
> > > > Remove the bottom cover of the radio after line cord has been unplugged and rig allowed to sit for awhile to ensure filter caps have bled off. The Aux Relay is about in center of radio next to two vertically oriented filter capacitors about on a line back from the VFO knob. The Ant relay is under a metal shield can in rear corner. You can remove both and clean contacts. Some folks rotate the position of these relays from time to time to place them in different service. Kens Electronics in Kalamazoo Mich has NOS replacements. He has a website. Not a bad idea to have a spare.

I forgot also measure voltage at Pin 6 AGL should be same as what you read at Pin 11 AGC.

Also apply temporary 3vdc to Pin 6 and see if S meter comes off the peg.

AGL and AGC at IF board should be same point electrically as they are connected in receive mode thru the NC contact of the aux relay you just cleaned. But possible to have bad molex connections at Relay board and/or IF board.

42291. Re: TS-520 Het Osc Measurements

Topic: 42266 Message: 42291

Hi Terry,

Just a quick reminder first that mine is the 520SE with no ALC on 28MHz and just a few watts out on that band, but 100W on other bands,

I just duplicated your Het Osc measurements at TP3, using Tektronix 2225 50MHz scope for p-p measurements.

I recall in earlier post you said het osc would be about 1V, but your readings are quite a bit higher. The ones I actually measure on my 520SE are:

3.5 = 3.0V p-p = 1.06 rms
7.0 = 4.6V p-p = 1.63 rms
14.0 = 3.2V p-p = 1.13 rms
21.0 = 3.6V p-p = 1.27 rms
28.0 = 2.6V p-p = 0.92 rms
28.5 = 2.6V p-p = 0.92 rms
29.1 = 2.6V p-p = 0.92 rms

So as you observed before, the 28MHz Het looks a tad low and needs alignment, but I note all readings well below your 1.6 to 1.7V rms.

Took your idea to "sniff" out the RF with finals loaded and pushing out the 5W or so I manage on that band. Just wrapped a few turns round the patch co-ax to dummy load. I got 28.000MHz on the counter, and the Plate control is at the 28MHz position.

You may need to ignore the previous readings I gave you for the Driver valve output at DP. Experimenting with other bands I could see that the scope probe was badly detuning the circuit. On 21MHz where I can get 100W out I could only see about 40V p-p (not 160!). I couldn't even get ALC indication with the probe in place. Moving the Drive would increase DP but still well below spec. I didn't see same detuning effect on 7MHz and got the full spec DP volts.

I cleaned the band switch with Servisol at the wafer on the Drive coil board, but made no difference (in any case does that frequency counter 28MHz reading show the band switch is ok and switching in the Drive coil?).

So I am hoping it is just that the rig has not had any alignment for many years, and that this will bring 28MHz back to life.

Thanks for all your help and suggestions so far.

I too have the Twins set and am also missing the darn cable. Must be chronic with the T-599/R-599. I would be interested in throwing into a batch buy of these cables in order to get one. That's if we can find a point person to start it all up.

Regards,

Jim L.

Adrian:

1. When I said 1 volt rms for Het Osc at TP-3 I am saying should not be very much less than that. On 40 meters you are right where I am at. My readings are approx .6 to .7 volts higher than yours. You can add a tenth or two for your bandwidth limitation of your scope. Likely just means I have just peaked them a little more up on the response slope. I use Boonton rf millivolt meter and then back off from peak approx 1dB. Absent instrumentation people will peak until they hear the oscillator stop and then back off 1 full turn or so.

2.OK just wanted to make sure the low RF output you were seeing was not due to being loaded on harmonic. With resonance occurring at normal indicated tank cap position and counter confirming fundamental frequency output not likely a problem inside the PA cage. Have you ever made a good visual inside the PA cage especially the two plate chokes and rf bypass cap? With all other bands good not likely a problem. No padder caps switched in on 10 meters, but suppose could have cold solder joint on the 10 meter tank coil?

3. Not unusual to slightly detune the Drive tube plate circuit when trying to measure rf levels at DP. Not sure why your scope probe works on 40 meters and not on 15 and 20 meters. Usually less effect at control grid of 6146 finals. The 830 Service manual recommends using a probe with no more than 3pf shunt capacitance. Might check your scope probe specs.

4. No you cannot tell by tank cap position if the Drive coil tuned circuit on 10 meters is being switched in. Really best indicator is when you can measure good 50 to 60 RF volts level at DP. I wish you had a 3 diode RF probe and VTVM to try to get that reading. Are you taking measurements with SG off, CW mode, Drive control and Car Level set for full scale ALC deflection? With my IM-18 and PK3 probe on 14.200 I measure very close to 60 rf volts and the ALC indication pulls off full scale meter deflection (350ma) down to approx 300ma when I apply the rf probe. The Boonton 92E pulls ALC indication down slightly less (310ma) and reads approx 58.5 rf volts. Note: using MA for reference.

Absent that will just have to wait until you get your tuning tools and then try peaking the 10 meters Drive and Mixer coils in TX mode and see if you can get some improvement.

I am reluctant to apply my new scope to the plate of the Driver tube to give you a comparison. It says max input voltage is 400vdc rms, but I am not ready to try that yet. I havent found the scope probe capacitance specs yet. Just had this scope for a couple of weeks and learning how to use it.

>
> You may need to ignore the previous readings I gave you for the Driver valve output at DP. Experimenting with other bands I could see that the scope probe was badly detuning the circuit. On 21MHz where I can get 100W out I could only see about 40V p-p (not 160!). I couldn't even get ALC indication with the probe in place. Moving the Drive would increase DP but still well below spec. I didn't see same detuning effect on 7MHz and got the full spec DP volts.

I do not suspect, but KNOW all too well, that you would be about as wrong as it is possible to be about that.

For the last fifteen years before being medically retired, I was all that the bean-counters and short-sighted politicians had left us of Tier Three technical support, as well as being in charge of all IT customer service center staff training for the IT department Hell(sic) Desk of a midwestern state-owned university; student population ca. 20,000 and a faculty and staff of around 7,000.

Plus another roughly 15,000 retirees which we also had to support, none of which to my knowledge could even FIND either one of a manual, or their own hind end, even with the aid of approach control radar and GPS capability.

I KNOW this frustration in my very bones.

It just is NOT worth the electrons required to send it to add in one more snarkish "RTFM" post, particularly when someone had already given the manual page and paragraph in a much more HELPFUL fashion in their post.

Just shouting "RTFM" over and over is simply a waste of time and bandwidth.

Next time, try the, "That's in the manual, page X, paragraph Y, where it says to .... " and skip the "RTFM YOU LAZY DOLT!" post. Or just send it to me if you have to vent, since I do understand the desire to strangle the lazy dolts.

Posting another "RTFM" to the list won't help; it only adds to the clutter.

Those who read manuals and How-To's, already do.

Those who don't, never will, and telling them to likely makes them dig in their heels even more deeply.

You may lead someone to knowledge, but you CANNOT make them THINK.

Thanks to everyone here already for the knowledge. Between the files area and the archives of previous trouble-shooting sessions, I may not need to ask a single question on the list.

The level of expertise here is higher than almost anywhere else I've found, on almost any subject matter. Give yourselves Kudos.

Hi Terry

This is all really useful and educational for me. I spent my youth building electronics projects do valves were always a closed book apart from experimenting with old small CRTs! It's fascinating to get to grips now with glass circuitry.

You may have put your finger on problem with scope probe. I am now away from bench for a few days, but I have a feeling the specs on the probe were not in single digit pF. I can check online with the probe supplier later.

For the DP voltage measurements you have flagged another error on my part. Yes I was measuring in CW and with SG off after tuning, but I was not taking ALC to full scale, instead setting carrier to where I would normally set when tuning the rig for operating with the needle a little past the ALC scale (on bands other than 10 metres the carrier needs to be around 9 o'clock to achieve this). When I'm back I'll see how this affects DP if I FSD the ALC. I don't think it will make much difference as when I was measuring low DP on higher bands I'm pretty sure I experimented with increasing carrier and didn't see more than very small change in DP.

So I'll go QRT for now on this thread, but am now really looking forward to doing a good alignment on all the coils. The tool should be waiting for me next weekend.

Thanks again and 73s

Adrian G4IQW

Adrian:

Yes you are correct it wont make much difference. Important to just be consistent on your measuring procedure from band to band.

Several opinions on how Kenwood took the baseline TX Level Diagram voltages. No one we can ask. Look at each Service manual from the 520 thru the 830 and you will see varying levels of descriptions of the test conditions that were used. There are also some obvious errors on them. Clearly all were taken around 14.200 mhz. This makes sense as in the middle of the rigs band coverage.

At a minimum I would make sure that the ALC indication was no less than at the far right maximum end of the black rectangular ALC range on the meter.

I always just set Car pot and peak Drive for meter full scale deflection (FSD). I have found that with a fresh Driver tube and spec dc tube voltages you should be able to easily get to this level of ALC indication and it should not drift down while keyed to take your reading. With exception of 10 meters you can usually get this with Car Level pot no more than 1100 to 1200 position.

I have done some measuring of RF drive voltage at the 6146 control grids with various settings of the ALC indication including 50% of ALC box, 100% of ALC box, and Panel Meter FSD. I got no more than 0.50 rf volts difference. I also measured grid current and found it ranged from a low of 30ua at 50% of ALC box, 32 ua at 100% of ALC box, and a high of 34ua at panel meter FSD on 20 meters. That is micro-ampere and not milliampere.

I did this because the owners manual up until the 530/830 always confused people as to where in the panel meter range you should peak the Drive Control. With the 830 they tell you to keep it inside the ALC box. They just had to pick a spot. I have even seen You Tube hybrid loading videos that caution that you should make sure the ALC indication remains at 50% of the ALC box or to never exceed the maximum range of the box as if something terrible would happen if it exceeded the far right end of the ALC range. See them go back and forth adjusting it to keep it in the ALC box. Even see them go back and check it again when all done loading to 100 watts out. Where in the manual does it tell anyone to do that? This can get them in trouble as they may have no ALC indication now due to negative feedback at 200ma (subject for another post). This is all silliness.

I always teach to increase Car Pot to give yourself something to look at and to work with. So 2/3 to 3/4 FSD is what I do when loading my rigs. All you are doing is peaking parallel resonant circuits. You dont have to worry about exceeding 6146 control grid current. This is not a Class C grid leak bias transmitter of old days where you had to make sure you did not exceed the 6146 grid current of 3 or 4 ma. You will never see more than approx 45ua grid current. The minute the control grid goes positive with respect to the cathode and grid current starts to flow the ALC bus voltage is reduced, TIF signal is reduced, and grid current never exceed ua levels. What you are looking at and peaking on the meter is the ALC bus line control voltage going down in response to this ua grid current flow from cathode to grid. At resonance of the tuned circuits you will have maximum rf drive voltage which

means maximum difference between control grid rf drive and DC bias offset. This means grid is at maximum positive voltage relative to the cathode on the positive envelope of the drive signal. You are not establishing some maximum level of grid current.

Anyway if you want to run TX level diagram by peaking the ALC at far end of ALC box you should be OK doing that. As I said I like to run it to FSD which tells me Driver stage is capable of doing so and sustaining it without drifting off. Just let Driver Tube rest a little in between readings on any given band and when switching between the bands. It is running Class A at or slightly above max 27ma plate current so will run pretty hot. I have never lost one running TX level diagrams, but it certainly is possible given how hard tube is being run. I keep several spares on hand.

I don't get that attitude. Maybe the best advice you can get is "read the manual first" ! It encourages you to think before you ask for help you may not really need and maybe it will help you keep from looking bad.

Well. I see that this list is not as I had first thought immune to the "RTFM" rant that seems to be so prevalent elsewhere.

Sad. I had such high hopes.

If there's a vendor that sells the connectors, we can make up our own
cables.
I'll look around again to find a vendor.

> I keep several spares on hand.

Is this a "generally recommended practice" or something needed only when doing voltage levels or realignment?

If a general sort of recommendation, which of the myriad tube suppliers that crawl out of the woodwork on a general search of the web are the most reliable for a U.S. purchaser? I've spotted some recommendations in the archives, but there might be others that people have good luck with, and that haven't yet made it there.

In any case I'll be getting at least one driver tube for a spare, and making a clip for it inside the chassis somewhere, lots of room in the box, so I'll always know where it is....

Also, in re cooling, the big fan in there seems to be working fine, but does it actually cool enough? Would increasing the cooling be of enough benefit to make it worth a small amount of effort? I can cabbage together a small squirrel-cage external blower to increase the airflow a lot, if it will help. (Allowing that this thing ever works again, of course....) Tube life is for me a definite consideration.

Seems we go through this exercise periodically.
Hirose Connectors:
http://www.hirose-connectors.com/
Digi-Key and Mouser are two major distributors.

Topic: 42266 Message: 42302

If you are asking about 12BY7A Driver tubes I have never purchased a new one for a Kenwood Hybrid. Cant recommend a source. Running TX Level Diagrams on all bands is probably most severe service they see. Lots of key down time to get complete set of rf drive readings on all bands.

This tube was originally used in the 50s as a TV video amp. Hams have been using them as a rf driver tube for pair of 6146 finals for years. Many of the commercial boatanchor transmitters used it.

I suppose I may have bought a new one or two back in the 60s, but all the ones I have now are supposed to be NOS tubes that I have picked up at hamfests and off Ebay. I service these rigs so I keep a stock for customers in addition for my operating TS-830 rigs.

A 12BY7A lasts quite some time considering they are biased Class A and are being pushed hard in hybrid service. If you measure cathode voltage and the cathode resistance and apply ohms law you will see that we are right at the recommended maximum plate current listed on tube data sheets. As they age and emission starts to fall off it first manifests itself on 10 meters. You wont be able to get as much ALC indication on key down and the ALC indication will begin to drift low under key down.

I dont think you need any additional fan. Just maintain it. I remove and clean and lube mine annually. The bushings are oil-lite bronze that depend on felt pads in each bushing housing. I disassemble and soak the felts annually. Any lite machine oil will work.

Some fellows are still running the original S2001 and S2001A tubes which tells me design cooling is adequate. Just observe good practice loading the rig. Avoid long keydown time, long off resonance tuning, dont exceed max plate current, and de-rate if using any high duty cycle modes like PSK. I have no experience with the new Chinese made 6146s. Problem we face today is all the NOS finals that you buy are 35 to 40 years old and may not be viable spares when you reach for them. I have experienced this and not fun. Arc over and accompanying blowing of cathode meter shunts is all too frequent.

I cant imagine storing the spare driver tube in the rig. Of course I am a neat freak and can walk to anything in my shack and shop.

I have been a member of this group for quite some time. But, now, I have a "new" TS-830s. I have considerable electrical/electronic experience, but not necessarily dealing with RF. However, I have searched the group archives may times. I haven't found an answer to the problem I'm having. BUT, I am very reluctant to ask for help on this forum for fear of being FLAMED. I really don't want to hear someone tell me how superior they are to me.

Chuck,

I totally agree with Gordon. When I started out here a couple of years ago...I got "flamed" a couple of times. I just
learned to tune them out...if it gets too bad...Gordon..n6wk..is a moderator...and can tune THEM out.

Salute to all the veterans..who made this day possible

Wes,

I agree with Terry. The driver tube takes a beating when checking drive levels. It's a good idea to keep a known
good driver AND finals around. Ken Kemski....k4eaa.com sells nos drivers...he is absolutely trustworthy...he also has some
goodies and a rather good Q&A section. I also have gotten stuff from "hybridrestore" but no tubes. RF parts are good. I will not say to buy
any particular brand...except to say that I have not had good luck with the Chinese 6146B's. Taylor sells them..with a guarantee...but
if the tubes arc over...and you pop the cathode resistors...that's your problem...easy fix on the 820..but a pain on the others

As Terry stated...that fan works fine...just keep it clean..and a few drops of good light lube in the holes. I have an
820S with the original S2001's still working fine. If you treat 'em good...they will give a good life span

  To all the VETERANS who made this day possible....THANK YOU!

Is this a "generally recommended practice" or something needed only when doing voltage levels or realignment?

If a general sort of recommendation, which of the myriad tube suppliers that crawl out of the woodwork on a general search of the web are the most reliable for a U.S. purchaser? I've spotted some recommendations in the archives, but there might be others that people have good luck with, and that haven't yet made it there.

In any case I'll be getting at least one driver tube for a spare, and making a clip for it inside the chassis somewhere, lots of room in the box, so I'll always know where it is....

Also, in re cooling, the big fan in there seems to be working fine, but does it actually cool enough? Would increasing the cooling be of enough

benefit to make it worth a small amount of effort? I can cabbage together a small squirrel-cage external blower to increase the airflow a lot, if it will help. (Allowing that this thing ever works again, of course....) Tube life is for me a definite consideration.

Chuck: Congrats on the 830s..I have one and have put my Icom-7000 back in the box. I added an MFJ-DSP filter, with nice results.

I don't agree that people are trying to show superiority here. We are all (supposed) to be licensed Hams, which should mean a certain familiarity with electronics and manuals. Unfortunately, there are some who don't even try the most basic of steps when they run into a problem, but immediately ask for detailed step by step instructions in troubleshooting and repair, while they have not even bothered to download a usually free manual.

Moreover, as Hams, they should understand the need for test equipment and tools needed for repairs, and not expect other people to remotely diagnose our problems without the possibility of making accurate measurements. When that happens (too frequently), a little "negative feedback" has been expressed. But no one has been insulted, asked to leave the group, etc.

This is the most interesting Ham group I've ever encountered, and people like Terry, Mike, etc. deserve all our thanks for their free, time consuming efforts toward keeping our 30-40 year old rigs going a bit longer. All they ask for are some reasonable basic fundamentals on our part.

My feelings, anyway.

Nice. Is there an outboard DSP that you might recommend?? (Maybe home-brew? Can you make one out of a Raspberry Pi module? Hmmm... GIYF, gonna have to look into this.) Something that would give my hopefully-repairable 520 a kick in the audio?

I've got some scavenged MFJ odds and ends (VHF/UHF SWR meter that only needed a new calibration pot and some peanut bulbs for the meter light for instance), and I'm not at all brand-conscious.

Back in the box..... Here I am scraping people's junk to get -anything- in working order. I guess maybe some of the slams I keep hearing from the young people I try to convince to give amateur radio a go are really true:

"It's only for RICH PEOPLE."

It's certainly gotten a lot pricier than when I was a kid, turning old five-tube 1940's vintage cabinet radios into piles of parts, then trying to make something new out of them. "A Two-Tube Superheterodyne SW Receiver From An Old Television!" kind of magazine articles.

Not much of that going around these days. I'm not sure it's an improvement, personally.

> Moreover, as Hams, they should understand the need for test equipment
> and tools needed for repairs, and not expect other people to remotely

Which is why I'm currently on the look-out for an old Simpson 303 or the like, or even a Heathkit that I can recalibrate. Cut my teeth on swing-needle VTVM's. I think I've gotten a little lazy with the digital meters, auto-ranging and all that silliness. The higher impedance will certainly help.

(AND while I'm waiting for parts to arrive, I've dug out the monster of a o-scope, which I've not used in a coon's age, and will be working on re-aligning and re-calibrating that old junker, as well. Here's hoping I don't wind up spitting sparks when I get the case off and fire it up. "One hand on the probe, the other hand in your back pocket.")

> This is the most interesting Ham group I've ever encountered, and people
> like Terry, Mike, etc. deserve all our thanks for their free, time
> consuming efforts

That it most certainly is, I can tell you that you're dead-right on that one; I got this much in the short time I've been here. There are some seriously high-forehead sorts in this group, and I'm really hoping that the archives in particular will get me a working radio pretty soon. I now at least have some hope, where going it alone was leaving me with none.

>> very reluctant to ask for help on this forum for fear of being FLAMED. I

My Previous Point Exactly.

Mention that the information -could- have been found on page whatever, and get on with the world. Making people feel like idiots may make you feel better, but it doesn't in the end do anyone else much good.

More than one of those "you could have gotten it on page X, but here is your info" messages is likely to give more impetus, and do more toward shaming the simply lazy into looking first, and the uninformed into knowing where to look in the first place.

Sometimes it's not a matter of "Won't be bothered to try, just spoon-feed me" but "WHAT MANUAL? WHERE? THANKS!"

That "transmit voltages" list for instance. I did not know where it was located, or if there was one available, until I heard it mentioned in passing in one of the postings here since I got hooked up a few days ago. Now that I know it exists, I know to search the archives and the file list for it when I get to that point.

Had I gotten started first with the repairs and asked about reference voltages at the various test points, I am now quite certain someone would have chortled gleefully (or snarled nastily at how stupid I was) while rubbing my nose in my not having found it for myself; when the fact is I didn't know for certain it existed anywhere public.

Knowing more than a little (too bleedin' much) about human (and radio-geek) nature -I- would have just shrugged it off and gotten on with things. Others without the hidings I've been through and less emotional scar tissue layered on would have more than likely just dropped out of sight and let their radio stay dead. And another nice old rig with a lot of good times left in it would wind up in the dump.

Yes, looking for the answers in the manuals and archives, that's the best way of going about things. But getting all bent about it when somebody doesn't do so, is it really worth the angst and anger?

It never got me an extra penny when I was troubleshooting Microsoft's junk for a living, even when the 'fix' was a matter of clicking a mouse on the "HELP" menu and typing a four- or five- letter word then following the instructions that popped up. After enough years of it, you learn to save the adrenaline for things it will actually help...

Point to the right place which this new/lazy/uninformed/whatever person needs, and let it -go-, that's all I'm saying.

If it's egregious, someone who thinks the world owes them and who is demanding coddling - instead of any thinking, then just don't coddle. Point to the manual once, or the archive where it has been done umpteen times before, or whatever, and let them figure it out. Or at least start asking the right questions instead of demanding privileges.

<shrug>

I just don't see where expending any big amount of emotion (anger, disgust, superiority, hatred, etc.) is helping anybody, excepting maybe the makers of blood-pressure drugs. And from the last bit quoted above, we can see that the "RTFM, STUPID!" approach IS doing harm to people who truly aren't trying to be annoying, (Even when the "stupid" part is not actually uttered, it is perceived to be there by the person on the receiving end. You can bet on that.)

And there's the last syllable I'm planning on saying on the subject; enough is too much, as Popeye said.

To the question on the DSP...

Pairing a Softrock SDR (around $25, or about $60 assembled) with just about any PC made in the last 10 years will give you a receiver that will wax 100% of the stuff made prior to about 1990. And a version of that same softrock can be stuck off the IF of any of the hybrids for the similar sex and sizzle of modern combined with old school.

I think it’s easy to make a case of amazing performance for little bucks thanks to the march of modern tech. Unfortunately, that same march of tech is slowly obsoleting yesterday’s soldering iron skills in favor of contemporary software.

fact is I didn't know for certain it existed anywhere public.

Knowing more than a little (too bleedin' much) about human (and radio-geek) nature -I- would have just shrugged it off and gotten on with things. Others without the hidings I've been through and less emotional scar tissue layered on would have more than likely just dropped out of sight and let their radio stay dead. And another nice old rig with a lot of good times left in it would wind up in the dump.

Yes, looking for the answers in the manuals and archives, that's the best way of going about things. But getting all bent about it when somebody doesn't do so, is it really worth the angst and anger?

It never got me an extra penny when I was troubleshooting Microsoft's junk for a living, even when the 'fix' was a matter of clicking a mouse on the "HELP" menu and typing a four- or five- letter word then following the instructions that popped up. After enough years of it, you learn to save the adrenaline for things it will actually help...

Point to the right place which this new/lazy/uninformed/whatever person needs, and let it -go-, that's all I'm saying.

If it's egregious, someone who thinks the world owes them and who is demanding coddling - instead of any thinking, then just don't coddle. Point to the manual once, or the archive where it has been done umpteen times before, or whatever, and let them figure it out. Or at least start asking the right questions instead of demanding privileges.

<shrug>

I just don't see where expending any big amount of emotion (anger, disgust, superiority, hatred, etc.) is helping anybody, excepting maybe the makers of blood-pressure drugs. And from the last bit quoted above, we can see that the "RTFM, STUPID!" approach IS doing harm to people who truly aren't trying to be annoying, (Even when the "stupid" part is not actually uttered, it is perceived to be there by the person on the receiving end. You can bet on that.)

And there's the last syllable I'm planning on saying on the subject; enough is too much, as Popeye said.

Topic: 42266 Message: 42310

I have a few comments about vacuum tubes which include spares and getting vacuum tubes.

If spares are purchased, it is recommended they be used periodically and not be allowed to lay/sit on a shelf for months and years at a time.Using the spares periodically allows the tube to heat up and absorb any gas that has accumulated over time.

A few words about shorted tubes and the symptoms they produce. Shorted small tubes such as those used in receivers, can cause loss of receiveas well as other stage failures, and produce a high static noise which can result in a high S meter indication. This is especially evident when the tube is used in the receiver's front end and IF amplifiers before the detector and S meter circuit. The only way to determine which tubeis bad is to take voltage measurements of each stage starting at the RF amplifier. At some point along the signal path the voltages will not be right. When that stage is found, replacing the tube with a known good tube will typically cure the problem. Small tubes are not excluded to overheated plates, color appears on the plate(s). No small tube, whether used for transmitting or receiving, should ever show any color onthe plate, regardless of how low level the plate color is. If the tube shows color on the plate the problem is either in the circuit itself or the tube.

Tube pin seals change over time which is caused by the heating and cooling around the pins. This results in gas in very small amounts entering the vacuum over time. There are folks who have been told to operate the tube(s) under filament voltage only for hours in order to absorb the gas accumulation. That process doesnothing but waste time. First, the filament in low power tubes such as the 6146, is not coated with a getter material. Second, the filament cannot and will not heat the getter element which is attached to the tube's plate, to the high temperature required for the getter material, Barium, to absorb gas. Third, current must flow in the tube (normal operation)for the plate to heat to the high temperature for the Barium to absorb any gas. Some tube that have excessive gas can arc in the base. I've experience 6146 tubes that have sat for years on the shelf "asspares", not being used periodically, that have arced in the base. This process occurs when the tube conducts and electrons are attracted to the positive ions in the gas resulting in an "Ion explosion" which can burn a hole right throughthe plate and also destroy the thin wire mesh in the grids (grid #1 and screen grid #2).

The getter element in the 6146and many other low power transmitting and receiving tubes, is also attached to the "Plate" and the filament cannot and will not heat the plate to the high temperature required to absorb gas. The only way the getter element can achieve a high enough

temperature is when current flows in the tube, heating up the plate. The "Chrome" or "Shinny" coating on the inside of the vacuum tube can change colors over time. Thisdoes not mean the tube is bad as some hams have been led to believe. The "Chorome" or "Shinny" coating is what occurs during the manufacturing process and is referred to as the "Getter flash". The air is removed from the glass envelope, the base of the glass envelope is sealed, and the tube is placed in a special machine which subjectsthe tube to a high RF field that heats the plate and getter element that's coated with Barium to the point where the Barium "Flashes". When the getter flash occurs, any residual air that exist after the base is sealed, is absorbed and the Barium on the getter element coats the inside of the glass envelope with a "Chrome" or "Shinny" coating. This process cannot be reproduced by the typical ham unless you have a thousands of dollars to purchase the machine that performs this process! The getter elements come in different sizes and shapes, a ring, a small round cup, or a squarewire, and they all are attached to the plate. If you look behind the "Chrome" or "Shinny" coating you will see the getter element which is attached to the plate by a spot weld during manufacturing. Any cracks in the tube's glass envelope that allow air to enter the glass envelope will cause the "Chrome" or "Shinny" coating to turn "White". When you see a tube where the coating has turned White, throw the tube away. The reason for the White color is because Barium turns White when exposed to air.

The getter material in high power tubes suchas the 4-400, 3-500Z, and 4-1000, is the dull dusty gray coating on the plate. The dull gray dusty coating is "Zirconium". Zirconium requires a high temperature, approximately 1000 degreecentigrade, for it to absorb gas. Like the low power transmitting and receiving tubes, that high temperature can only be acjoeved when current flows in the tube, heating the plate. The filament heat cannot and will not heat the plate to the high temperature required for Zirconium to absorb the gas. no matter howlong the tube is operated with filament voltage only! The plates on these higher power tubes are designed to take high temperatures so during normal transmissionsif you see the plate of these high power tubes showing adull red glow, don't be alarmed, that's normal. Some hams have been led to believe that when this occurs they should reduce drive so the color disappears because the dull redglow indicates over driving the tube. That's not true. Reducing drive is the worse thing you can do to these tubes, transmitting with no color showing! Reducing drive results in a reduction in current flow in the tube which lowersthe plate temperature ultimately resulting in the Zirconium to stop absorbing gas. High power tubes can arc but not all arcs mean the tube is toast.For further discussion on arcing in high power tubes I recommend reading Tom Rauch, W8JI, website(www.w8ji.com) where he has pictures showing arcing in high power tubes and the damage arcs can produce.

Another thing about spares. Don't waste your time buying "Matched tubes". The only time Matched Tubes are recommended is in "Push Pull" amplifiers. NONE of the hybrid final amplifiers operate in "Push Pull", the all operate in "Parallel". Matched tubes are a waste of money and

you will not achieve any improvement by wasting your money buying
Matched tubes.

A word about tube testers. Most tube testers only test for filament
shorts/opens, shorts between the elements, and simple conduction. Tube
testers do not and will not test tubes under RF conditions. The only
real tube tester is the circuit the tube's used in, providing the
voltages and signal levels are correct.

A word about gassy tubes. Gassy tubes can affect how the circuit works.
Gassy tubes tend to cause the grid to be more positive which causes the
to conduct more than it should. This typically affects the grid which is
the element that controls current flow in the tube. The gas allows
electrons to flow between the cathode and the grid making the grid "less
negative" resulting in the tube conducting when it shouldn't. A simply
method to determine if a tube is gassy or not is to measure the grid
voltage (no signal applied) on both sides of the grid resistor. If the
voltage on the grid side of the resistor is "less negative" then the
voltage on the opposite side of the grid resistor then the tube is gassy
and should be replaced. A good, non-gassy tube, will have the same grid
voltage on both sides of the grid resistor. Most grid resistors,
excluding the "grid leak" resistor in an oscillator, are used to isolate
the grid fromthe AGC or ALC bussand are typically 1 meg 1/2 watt. These
are used, forexample, in RF and IF stages where the AGC and ALC voltage
control gain.

The TS 830s vox is working fine. The problem I have is on cw. I automatically send cqs. I would like the delay to be long enough where the relay does not drop in and out. With the delay at max, I am having the relay cut on and off. Is there an internal adjustment that will allow the delay to lengthen.

Thanks

Wes: The MFJ is an outboard = MFJ-784B....many features and does a great job. You can get one used on eBay, eHam, etc anywhere from about $125 to over $200 used. Sorry, I don't have any info on home brew DSP, but I'm sure it's out there...

Yes, the world has changed since we were young...

Bob:

You are the kind of Ham that makes it rewarding to make the time commitment. I never subscribe to knowledge is power. We are trying to teach a way of thinking and acting and you clearly understand it. I freely share any thing I know or have experienced. I do this so someone can take my place holding the tent poles up and keep these classic treasures on the air and keep a small portion of the old hobby alive that I was lucky to grow up in.

Thank You
Terry K9TW

I agree with Mike and now rotate my spare finals once a year when I do my annual PM (cleaning, VFO tri-flo lube, fan bushing lube etc). Also he is correct you cannot getter the 6146 finals. If you want to "cook" them have a ball, but not possible to really "getter" them.

I do not rotate the 12BY7A driver tubes.

I use to place any spare 6146 final I bought in my Heath DX-60 to run them with anode and screen voltage on and RF excitation and some plate current. I quit doing that as the DX-60 doesnt really replicate what the 6146 sees in Hybrid service. My thought was it was better to experience a arc over in the old DX-60 than in the hybrid, but in practice it didnt prevent arc overs.

I am now a fan of DC hi-potting or BVT testing, but very few hams have this test gear. You could charge up a high voltage cap and dump it across anode to cathode but not recommended if dont understand what you are doing. Work the math with a .002 uf cap and you will be surprised how many joules is involved.

So rotating tube in service time seems best alternative for most hams.

You may also want to consider installing some arc over protection. I have done this in all my rigs and havent experienced any more blown cathode resistors.

Terry,

Please give us some details about the arc over protection that you have installed in your rigs. This sounds potentially very helpful.

Thanks,

Louis

Subject: [TS-520_820_530_830] Re: TS-520 Het Osc Measurements

I agree with Mike and now rotate my spare finals once a year when I do my annual PM (cleaning, VFO tri-flo lube, fan bushing lube etc). Also he is correct you cannot getter the 6146 finals. If you want to "cook" them have a ball, but not possible to really "getter" them.

I do not rotate the 12BY7A driver tubes.

I use to place any spare 6146 final I bought in my Heath DX-60 to run them with anode and screen voltage on and RF excitation and some plate current. I quit doing that as the DX-60 doesnt really replicate what the 6146 sees in Hybrid service. My thought was it was better to experience a arc over in the old DX-60 than in the hybrid, but in practice it didnt prevent arc overs.

I am now a fan of DC hi-potting or BVT testing, but very few hams have this test gear. You could charge up a high voltage cap and dump it across anode to cathode but not recommended if dont understand what you are doing. Work the math with a .002 uf cap and you will be surprised how many joules is involved.

So rotating tube in service time seems best alternative for most hams.

You may also want to consider installing some arc over protection. I have done this in all my rigs and havent experienced any more blown cathode resistors.

Louis:

Go to Ron WB4HFN site and click on Kenwood Net Home page and then click on Articles.

1. Installed diode string across the cathode resistors to protect the panel meter and the resistors. Tom Raunch W8JI gave me this idea.

2. Installed MOV (varistors) from screen grid to ground. I copied this from G3SEK Tetrode Board protection. If you get serious I can share the calcs I performed to size the MOVs.

3. Installed Ohmite OY glitch resistors at output of HV filter caps to limit fault current. Eimac Care and Feeding white paper prompted this idea. With out these resistors fault current is only limited by the 5 ohm cathode resistance and low value of transformer ESR. 900vdc/5 ohms = 180 amps. Add 10 ohms of glitch resistor then 900vdc/15ohms = 60 amps

I ordinarily do not recommend modifying these rigs, but threw in the towel after multiple cathode resistor failures on 520, 530, 820, and 830 rigs with a variety of brands of 6146 finals.

Havent seen any recent posts on this problem so maybe the disease has been cured ?

I meant "popping" your 6146 with a 0.2uf hv cap charged to 900vdc. Would not use anything larger.

Back of envelope calcs;

Joules = W = 1/2 (uf)(vdc)squared = (.2 x 10-6 UF)(900vdc)sqrd = 81 milli joules

Assuming 5 micro second discharge time then:
Power = joules/time = (81 x 10-3)/(5 x 10-6) = 16,200 watts

That will vaporize any "wiskers" !

Terry K9TW

"You could charge up a high voltage cap and dump it across anode to cathode but not recommended if dont understand what you are doing. Work the math with a .002 uf cap and you will be surprised how many joules is involved".

Better to build or buy a BVT or Hipot tester.

Does anyone happen to know of a replacement part number for the power connector for the DG-5? (Kenwood number E08-0203-25). If anyone knows the manufacturer, that would help also. I need several plugs only. I know of one enterprise that is selling the complete cable kit for around $25. I am hoping for a more cost-effective solution. Thanks

Jerry KJ6NTL,

Thanks for the good advice. I usually do take pictures of things, and label the heck out of them when I have any doubt I will not be able to put it back together. In this case, I did not realize there were extra male pins not being used (they where kind of hidden behind the chassis and I missed it). But it's always a great idea to take photos of things as you take them apart, I agree. :-)

Mike,

I apologize for not finding this in the manual. I have read the manual several times since I got my old rig a month or 2 ago; used it for tuning my rig, find out specs, etc, but I did not remember this figure. To be honest, I don't think I would have known how to even look for my problem in the manual, as I know not all connectors of all boards are shown in figures in the manual. I thought I had messed up, and only someone who knew the boards could confirm where the connectors go.

Again, I apologize if I wasted anybody's time.

Thanks Terry. I'll read up on this. At first glance, mod #3 appears very easy. The other mods require more careful work. Do you think that mod #3 alone would be beneficial?

Subject: [TS-520_820_530_830] Re: TS-520 Het Osc Measurements

Louis:

Go to Ron WB4HFN site and click on Kenwood Net Home page and then click on Articles.

1. Installed diode string across the cathode resistors to protect the panel meter and the resistors. Tom Raunch W8JI gave me this idea.

2. Installed MOV (varistors) from screen grid to ground. I copied this from G3SEK Tetrode Board protection. If you get serious I can share the calcs I performed to size the MOVs.

3. Installed Ohmite OY glitch resistors at output of HV filter caps to limit fault current. Eimac Care and Feeding white paper prompted this idea. With out these resistors fault current is only limited by the 5 ohm cathode resistance and low value of transformer ESR. 900vdc/5 ohms = 180 amps. Add 10 ohms of glitch resistor then 900vdc/15ohms = 60 amps

I ordinarily do not recommend modifying these rigs, but threw in the towel after multiple cathode resistor failures on 520, 530, 820, and 830 rigs with a variety of brands of 6146 finals.

Havent seen any recent posts on this problem so maybe the disease has been cured ?

Hi Chuck,

No this group is terrific and there is no worry about being “flamed”. When I first got my TS-830S which had a number of problems, I was given enormous help by Terry, who was very patient as I would run tests and give him the results on this forum. This is one of the best of the ham radio forums in my opinion. I am no electronics expert, but I do follow the advice of people on this forum, order the manuals and try to trace the schematics-and it has worked for me!

Thanks and 73s, Scott, N6CIC

Louis they are all pretty easy to install. I just used solder lugs with star washer ends and used existing board mounting screws to mount them. Then tack solder the MOVs and Diodes to the tube socket pins and thru the solder holes in the solder lugs. Then dress the leads so not contacting or shorting anything. Not pretty but functional.

If I was to install only one mod it would be to protect the panel meter by not allowing the cathode resistors to blow open. Very easy to place 3 silicon rectifier diodes in series from tube socket cathode to chassis ground.

When Cathode resistors pop open the cathode will try to rise toward anode voltage. Assuming bias is still on the tube it will rise to well over 100 volts very quickly. Next time your cathode resistors pop connect your voltmeter to cathode and chassis ground and turn rig on and turn on heaters and watch the voltage climb. It will make you a little nervous. The 500ua meter movement is configured as a voltmeter and the max it likes to see is 1.75 vdc. They are expensive and getting hard to find.

In theory the diodes will clamp the voltage to approx 2 volts (turn on voltage for 3 silicon rectifiers in series) across the 5 ohm resistors and they will then see only 2/5 = 400ma instead of hundreds of amps. At that current level the Cathode resistors should never open again. Now the diodes may fail, but OK to sacrifice them and easy to replace them.

Even high power linear amplifiers that use glitch resistors and fuses in the B+ line normally also include some form of panel meter protection such as back to back diodes across the meter.

Work the math with a .002 uf cap and you will be surprised how many joules is involved.

Does anyone happen to know of a replacement part number for the power connector for the DG-5? (Kenwood number E08-0203-25). If anyone knows the manufacturer, that would help also. I need several plugs only. I know of one enterprise that is selling the complete cable kit for around $25. I am hoping for a more cost-effective solution. Thanks

Cesar,

No problem, no apology necessary.

A good thing to remember is to look at the pictorials in the manuals, a lot of questions can be answered in those pictorials. The service manual also has pictorials that will show you where the individual stages are located. Just be careful when pulling the plugs from the boards/enclosures. I use Hemostats clamped in the middle of the plus, pulling straight up. Hemostats are those clamps used by surgeons to clamp arteries closed during surgery. You can find them at All Electronics, www.allelectronics.com, and other outlets on the web. I use them for all sorts of task, holding resistors in place while soldering, picking components up that have fallen into the radio, and as heat sinks when soldering solid state devices. They are your 3rd hand when repairing your gear. They are also good to hold a piece of wire when cleaning solder out of PC board holes.

If in doubt and you can't figure it out or understand what's being said, can't find any reference in a manual(s), then by all means come and ask.

I had an 820 a while back, bought it on ebay 10 years ago. It looked like a previous owner painted it with a "paint brush" an awful light blueish green color, it was awful! It had other problems, very dirty VFO varicap shaft to frame connection causing instability in the VFO tuning, and the AF AVR board 9VDC supply pass transistor had on leg in the board hole and the other in the trash can. I fixed everything, used it for a few years, the sold it recently to a ham back east. Some of the intermittent problems, not all of them, can be traced back to interconnecting pin inside the PLL and display enclosures. The PLL and Display Unit enclosures have 2 boards that are "sandwiched" into the small enclosure with fixed pins making the interconnections.These connections almost never get attention and over time they become dirty resulting in intermittent failures. Kenwood also had problems with very thin foil runs which can be damaged very easily by using excessive heat. Cracks in foil runs in and around the plug pins are not uncommon. A lot of the boards have had updates done at the factory so when replacing a board it's very important to look on the "foil side" for the board's version number. Don't rely solely on the component side X50.... number, check the foil side number. This is especially important for the AF AVR board because there are 2 different board versions. Laying on the 2 different version AF AVR boards on the bench, side by side, both boards look almost identical but one board will work while the other will not. The change in on the "AF3" pin connections. The one thing I remember about the 820 AF AVR board differences is the audio is routed from the

AF3 connection differently on one version then the other. So don't forget to check the foil side numbers to ensure they match the replacement board. This, by the way, is NOT in any 820 operator's or service manual nor have I found this in any Kenwood tech bulletin, it's all based on my previous experience working with the 820's AF AVR board replacements. I no longer have the 820 but one day I may fine another and buy it.

The 820 service manual leaves a lot to be desired not only in accuracy but also in Japanese to English translation. Having said that, I do recommend taking some time and reading the "Circuit Description" section and study the block diagram so you get a better idea of what's going on "under the hood" of your 820. This also, after you have a good understanding of how the 820 works, will give you a better idea where to look when problems do arise.

It's also important to learn how PLL's work since the 820 is controlled by PLL Unit. It's important to understand that the PLL Unit requires 3 signals, VFO, CAR Unit, and PLL Unit's individual band's HET OSC signals to work properly. If just one of these signal is missing then the PLL Unit will change to an Unlock state resulting in no receive and no transmit. The 820's PLL unit is the easiest to learn and understand. Once you have a solid foundation on how the PLL work, learning how the 530 and 830 PLL Units work is much easier.

Having some test equipment is a must, frequency counter, analog VTVM, millivolt meter with RF probe (Terry has the details on one of these), signal generator, and a scope should be part of your test equipment collection. A DVM can be used but it's best used when measuring resistance and AC/DC voltages. For simple continuity checks, a cheap analog VOM found at your local hardware store is nice to have, simple and easy to use plus it has an analog meter. Most of these VOMs have one resistance setting, 1K. That's more than enough for any continuity checks you may need to do. I also use a DVM to measure power transformer winding resistance. You can tell if a power transformer is good or not by measuring the winding resistance and shorts between windings and shorts between windings and the transformer's metal core. It only takes a short between a couple of windings to cause excessive current to flow in the transformer. For more information on power transformers and how they work, including discussions on "back emf" magnetic fields, find a copy of John T. Fryes "Basic Radio Course". A seller on Ebay is selling the 1951 edition on CD. I recommend it since it's written in easy to understand chapters with simple examples. It's also a very good book/reference for those who are interested in learning basic electronics. I highly recommend it for anyone who wants to become a ham and learn electronics!

Have fun and enjoy your 820, they're a nice rig. They will drift which is normal for any analog "L/C" VFO.

One thing I have learned about using hemostats for electronics. They come with RIDGED jaws, for gripping strength, to make the blood vessel hold still when you pinch it off. This is good and bad for electronics. It grips really well, but can mar a wire or component lead so badly as to weaken it severely. Snap.

Pinching a light-gauge wire with the insulation on will show you just how much damage it can do. The ridged jaws will cut the insulation, small slits, as often as not. This leaves a possible short across another component or connection for your future trouble-shooting pleasure. Un-funny, to say the least.

I have several sets, saved from suture kits that are mostly just "throw-away" items now (where they were once sterilized and re-used). I run them through the wash, then the autoclave to sterilize them, and put them in the toolbox.

About a third of them I take to the shop in the basement and, using a water-cooled blade-sharpening wheel, grind the ridged jaws smooth. They still grip quite adequately, they still make wonderful soldering heat-sinks, but they no longer mar the wires and leads.

The R-599/T-599 interconnection cable used the Hirose 1300 series type of connectors (round pins). These were discontinued many years ago. Your best bet is to use the current Hirose 1600 series of connectors (flat pins). However, you would also have to change out the connector on the R-599 and T-599 to match the cable connectors. Doable stuff, but not trivial.

42330. FLAMED

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-29 04:01:59 UTC
From: rkings1956
Topic: 42330 Message: 42330

This is a reminder for people who say that no one gets FLAMED in this group for asking a question. This is the response I received this April when I asked a question about the plate current on the TS-530s.

Rob
KD6FSK

Plate CURRENT IS NOT THE SAME and IT IS NOT 225 ma FOR A TS-520.

For GOSH SAKES we are ham operators. This is a technical hobby. Read your owners operator manuals and if still uncertain then come here and ask. It is all there in front of you. Your manuals should be dog eared.

TS-520, TS,520S, TS-520SE and TS-820 Transmitters are all rated at 160 Watts DC Input Power. You load these to.... "ABOUT 200 ma"

TS-530 and TS-830 Transmitters are rated at 180 Watts DC Input Power. You load these to.... " Reduce the Carrier Control setting if Ip is over 265 ma"

1. Where did 225 ma come from? Ken Kempski K4EAA in his FAQ section suggests that 800v X 225 ma = 180 watt dc input power and it is pointless to exceed this level as it wont make perceptable difference on the receive end of a transmission and loading to this level (assuming proper loading technique) can extend final tube life. Without saying it Ken was obviously speaking about TS-530 and TS-830 rigs as they are the only two models with 180 watts dc input ratings. He would not recommend loading to 180 watts dc input power on a radio designed for 160 watts dc input power.

2. Why are the early rigs rated at 160 watts dc input and later rigs at 180 watts dc input? I Do Not Know With 100% Certainty. What I Believe is that it is due to the switch from S2001A finals to 6146B finals. I Believe 6146B tubes have higher Plate dissipation ratings. I have never seen a S2001A Data Sheet and do not know there plate dissipation or any of there ICAS max ratings. If anyone has one please send to Gordon N6WK so he can post on his site.

3. Is there any difference in the HV power supply capacities? No apparent or published differences that I have seen. Maybe we can ask Bob Mansker to hack transformers out of these rigs and weigh them to see if difference in copper and iron? Transformer weight roughly corresponds to KVA capacity.

4. Sorry about my frustration. This is suppose to be a thinking mans hobby. You have to be able to read and read with comprehension. Lacking this ability you are in trouble. Very easy to just ask and expect an instant answer with out doing any modest amount of homework. Maybe it is a age and cultural thing? I prefer to help those who are willing to help themselves.

5. Lets stop putting wrong information out on this forum. Easy to just "Parrot" what you have heard. This is how tribal myths perpetuate. If you are going to respond do so as an

"expert" or do so by qualifying your response. I will try to remember to preface my remarks by telling you what I "know" first and then what I "believe". Can be a big difference between those.

One of the worst things you can do is tell people what you know to be fact only to find out later you were wrong. Pity the poor Flat Earth folks!

Terry K9TW

Good morning,
Let's not start this crap again. Unless you find error in any of the info I would suggest printing and filing it in the notebook you should be keeping. This is a technical hobby. Some of these guys are experts and I for one appreciate their willingness to help me. Besides, none of them are as tough as my old Elmer. Now, let's put on our big boy pants and pay ATTENTION. Stop acting like children. Of course, this is just my opinion. Yall are free to do as you see fit. Enjoy the rest of the day God has given us.
73 yall, from K5HFG DON

If you consider this getting "flamed" you are going to get your feelings hurt daily in this old life.

This is a technical hobby that use to have high entry level requirements. If you dont have the bug and a passion for learning you are in wrong hobby and certainly have purchased the wrong radio. Yahoo forums by design provide a place for people with parochial interest.

If the charter of this forum is to serve as a "Help Desk" for the general public or appliance operators who are staring at a electronic black box trying to figure out how to turn it on with the manual on the floor then I dont care to be a member of that club.

If you cant open your TS-530 instruction manual and read the transmitter section on how to tune and load it including the maximum full load current you should sell your hybrid. If you read the instructions and have some questions about what you read that is an entirely different matter and what this forum is for.

My idea of this forum is the members share a common bond. A love of Kenwood Hybrids and desire to keep them on the air. They are above average intelligence and they come here because they want to learn how to operate the rig properly, how to maintain it, how to troubleshoot and repair it, and most importantly learn how it works. You wont accomplish any of that without some effort.

To accomplish that requires something between the ears and a willingness to do a little work. There can be no real learning if the student has no aptitude, no interest, and no work ethic.

If that is not what this forum is about then I am sorry. My mistake.
I am not interested in sitting on a "Help Desk" for the general public or appliance operators who just want an answer.

Strongly suggest you sell your Kenwood hybrid and buy a no tune solid state rig and have fun with it. That way not much chance of getting your feelings hurt by a teacher who has some expectations for you. If it breaks throw it away and get a new one.

Man it is sad what has happened to this hobby. I would love it if I could find just one young person to mentor who was a voracious reader, had a questioning attitude, had a gleam in his eye and fire in the belly, and would not go crying down the hall like a little sissy when he was pressed to do a little work. I guess that was a very different time.

Terry K9TW

Hi Terry,
Please don't rise to the bait. We all appreciate what you and many others contribute to this group.

Moderators,
Please stop this thread.
This group was founded for the repair and maintenance of our hybrids, no flaming allowed.
Bill would turn in his grave.

Thanks
Dave f4eyk

Sorry, but that gave me a chuckle.

That was the politest "FLAME" I have ever bloody seen. Even included an apology for "frustration."

If that's the worst it gets in here, well, you ought to count your blessings and then spend some time on some of the USENET forae I've been on over the years....

The flames there will take the hide off of you, and no mistake.

Agree with every word of this.

Especially the "what has happened." I have been told by some of my Boy Scouts in previous years (not doing the BSA thing for some time now) that Ham radio is strictly

"For old, fat, rich, white guys."

I find that ineffably sad. All too true a lot of places in the U.S., unfortunately.

If you want to help bust that image up, do what I'm trying to do at my wife's school. (She is a teacher at a rural consolidated school district.) In the High School Physics and General Science classes next fall, I am being allowed to give a pitch for Amateur Radio, with a goal of setting up a club, complete with their own shack in a small, unused room in the school building.

This is precisely why I am wanting so badly to get this 520SE back into service. It's going to be the HF rig for a bunch of kids, I hope, as well as for my own use.

I have scrounged and repaired an antenna tuner, HF SWR meter, VHF/UHF swr meter, an ADI junker of a 2-meter mobile which I've mounted in a box to make it also semi-portable, and a 45-ampere DC variable voltage, current-limited power supply. I'll be keeping an eye out for 2-meter all-mode gear and something for use on 220 and 70cm, for later on.

(The power supply is the only bit of kit already in hand which still needs some work, the current limit pot is wonky, needs to be replaced and then the built-in meters calibrated. Nothing an hour on the bench won't fix.)

I'll be needing to get them an oscilloscope, signal generator, VTVM, and a DMM for their shack-to-be. That's a fur piece down the road, though. I have to get the kids involved and interested in it, first. That

means getting a radio working and an antenna up, enough to make some contacts and catch their interest a bit. Packet and other digital modes are high on the list to get in the early innings, too.

(I need to get a replacement o-scope for myself, too, but that will have to wait; the 60's vintage clunker I have still works, more or less, though calibration is getting to be dicey. Still gives you a ball-park idea of the wave form, but I am not counting on the measurements being correct any more. It's so old that it's not just a re-alignment job either. Can't just rotate the yoke a bit to square up and level the trace against the graticule and get on with things any more. The calibration circuit is first to get fixed, it's seriously out of kilter.)

If you're looking for a challenge, and some kids who can carry on the hobby, you might try going this route. Your "fire in their belly" line is exactly why I went to the school board last month about doing this. They are giving me a chance to stir up interest, and see where that leads.

Maybe there is a school in your area that could get the same treatment? It's certainly going to be a challenge to get them set up and running, with the budget I've got to work with. (Which is of course ZERO DOLLARS, there are no extra funds for anything except a sport in the state of Illinois. Zero bucks to work with, excepting what I can free up out of my own pocket. The young'uns will be having to wash some cars or something for any gear they get once the club gets on its feet.)

(IF the club gets on its feet.)

I agree 150%. Well said and it's the truth whether some of you believe it or not! We're not here to "coddle" you, treat you with kid gloves so your feelings don't get hurt. We are here to help but we are NOT here to do YOUR part for you! We expect YOU to put forth effort on YOUR part and "YES" that includes reading the manuals FIRST. If you are being told the same thing on other ham forums that you are being told here, then don't blame us for your mistakes, take responsibility for your inaction! If you are not willing to do any of this, expect us to do ALL the work for you, then complain/whine when you don't get the answer you expected and your feelings get hurt, then this group is not for you, it's that simple!

If you consider this getting "flamed" you are going to get your feelings hurt daily in this old life.

This is a technical hobby that use to have high entry level requirements. If you dont have the bug and a passion for learning you are in wrong hobby and certainly have purchased the wrong radio. Yahoo forums by design provide a place for people with parochial interest.

If the charter of this forum is to serve as a "Help Desk" for the general public or appliance operators who are staring at a electronic black box trying to figure out how to turn it on with the manual on the floor then I dont care to be a member of that club.

If you cant open your TS-530 instruction manual and read the transmitter section on how to tune and load it including the maximum full load current you should sell your hybrid. If you read the instructions and have some questions about what you read that is an entirely different matter and what this forum is for.

My idea of this forum is the members share a common bond. A love of Kenwood Hybrids and desire to keep them on the air. They are above average intelligence and they come here because they want to learn how to operate the rig properly, how to maintain it, how to troubleshoot and repair it, and most importantly learn how it works. You wont accomplish any of that without some effort.

To accomplish that requires something between the ears and a willingness to do a little work. There can be no real learning if the student has no aptitude, no interest, and no work ethic.

If that is not what this forum is about then I am sorry. My mistake.
I am not interested in sitting on a "Help Desk" for the general public or appliance operators who just want an answer.

Strongly suggest you sell your Kenwood hybrid and buy a no tune solid state rig and have fun with it. That way not much chance of getting your feelings hurt by a teacher who has some expectations for you. If it breaks throw it away and get a new one.

Man it is sad what has happened to this hobby. I would love it if I could find just one young person to mentor who was a voracious reader, had a questioning attitude, had a gleam in his eye and fire in the belly, and would not go crying down the hall like a little sissy when he was pressed to do a little work. I guess that was a very different time.

Wes:

I thought about approaching the schools and like you I have the time but not the budget. Very recently I was a little discouraged when had 18 year old nephew in the shack and gave him a demo including working a Russian station while he was here. He liked the service bench but when all done and we were outside looking up at my tri-bander on the tower he pulled out his cell phone and pointed at it and told me he still didnt understand why I went to all the bother!

I dont have any integration of computer other than do use my lap top and audio spectrum analyzer software for LSB/USB carrier adjust. I wish had SDR and IF connection and pan adapter to show him as an example of how it relates to his world. He is heading off to college and I encouraged him to check out the campus club station. Hope he does.

I will think about your approach and interested to here off list how it goes. Went to club meeting recently and saw 8 or 9 old guys like me and a couple guys maybe in 30s and two meters was the talk. No 16 year old kids there and no hybrids in sight.

Take Care
Terry K9TW

I have two sons, now aged 21 and 25. They have been "surrounded" by Ham Radio, electronics and audio, computers, etc. since they were born. Neither has any interest in radio nor electronics.

In answer to the cell phone, I usually answer that meat is available in stores, which works for most people, but some people still like to hunt and fish....the world has changed, and the internet is producing many more changes, not always for the best.

II believe, also, that things like SDR, digital modes, may be a great way to the youngsters back into our Hobby..

Subject: [TS-520_820_530_830] Re: FLAMED

If you consider this getting "flamed" you are going to get your feelings hurt daily in this old life.

This is a technical hobby that use to have high entry level requirements. If you dont have the bug and a passion for learning you are in wrong hobby and certainly have purchased the wrong radio. Yahoo forums by design provide a place for people with parochial interest.

If the charter of this forum is to serve as a "Help Desk" for the general public or appliance operators who are staring at a electronic black box trying to figure out how to turn it on with the manual on the floor then I dont care to be a member of that club.

If you cant open your TS-530 instruction manual and read the transmitter section on how to tune and load it including the maximum full load current you should sell your hybrid. If you read the instructions and have some questions about what you read that is an entirely different matter and what this forum is for.

Terry,

The kids don't see any need for ham radio anymore. They have their cell phones and internet message boards.

We have two radio clubs in the Seattle/Tacoma area. People join these clubs because of the 2M FM repeaters. The cost of a 2M FM transceiver less than $200. Modern SSB HF transceivers is much more.

Then there is the problem of HF antennas. HF antennas in an apartment environment is almost impossible. just ask me! Most new homes have HOA restictions that make a decent HF antenna difficult.

I suspect that the few young people the do find an interest in HF buy a boatanchor like the hybrids do so because the cost is lower than a new RICEBOX. But most of these boatanchors purchased on eBay have some kind of issues.

Somehow I get the feeling that the Kenwood hybrids have more problems than the Heathkit SB /HW units. For one thing I don't see the PCB/connector problems with the Heathkit units.

The Drakes have a completely different set of problems.

The other problem is most of these people do not understand analog electronics or electronics at all. They often cause more damage to the units they are trying to repair.

Wes:

I thought about approaching the schools and like you I have the time but not the budget. Very recently I was a little discouraged when had 18 year old nephew in the shack and gave him a demo including working a Russian station while he was here. He liked the service bench but when all done and we were outside looking up at my tri-bander on the tower he pulled out his cell phone and pointed at it and told me he still didnt understand why I went to all the bother!

I dont have any integration of computer other than do use my lap top and audio spectrum analyzer software for LSB/USB carrier adjust. I wish had SDR and IF connection and pan adapter to show him as an example of how it relates to his world. He is heading off to college and I encouraged him to check out the campus club station. Hope he does.

I will think about your approach and interested to here off list how it goes. Went to club meeting recently and saw 8 or 9 old guys like me and a couple guys maybe in 30s and two meters was the talk. No 16 year old kids there and no hybrids in sight.

Take Care
Terry K9TW

I used my TS520 for 40 years without any digital display and I did fine. If you know how to use the Xtal Calibrator you can't go wrong.

Does anyone happen to know of a replacement part number for the power connector for the DG-5? (Kenwood number E08-0203-25). If anyone knows the manufacturer, that would help also. I need several plugs only. I know of one enterprise that is selling the complete cable kit for around $25. I am hoping for a more cost-effective solution. Thanks

Terry
I am brand new to this thread. I have been out of the hobby for 15+ years. After retirement and a few moves I decided it was time to put up an antenna and get back on the air. Time to dust off my first station, an 820 with SM-220 etc. I also have a later Kenwood non hybrid. Last week my 16 year old grandson was visiting and I gave him a chance to witness a contact with the Indy 500 special event station and a contact with Venezuela. He said "Wow that is better than a phone" He of course is a world away from knowing what that box will do or what is inside. Don't know if he has ever seen a tube. The digital world has changed the land scape drastically. If you have had your license and hybrid for 30 to 40 years you certainly will have a love for what you did to get your license and how you use and used your equipment. It was eye opening to me to read about the mods on this thread to protect the hybrid radios. I would like to see a little more patience from those that are really knowledgeable about these radios in leading some of us that need a little guidance on keeping them running efficiently. And yes I can read the Manual.
Liked the K5MYJ comments by Bob, pretty much on the mark. Analog electronics and a place to learn it is a slowly dieing technology.

Just saw this link for what looks like preliminary preparation for a launch of a 'new' Heathkit. You may want to check it out. Good luck to them.

Away from the flaming,

Terry and I have talked privately many times in the past. I am jealous of the test lab he has.

But I also have a decent one and I know how to use all the equipment.

I don't approve of people with out knowledge and test equipment trying to repair these radios. If they really want to do it they need some basic test equipment. I find that most of my needs are filled by Heathkit test equipment. About 10 years ago I started rebuilding my lab off eBay. I did buy a couple pieces that were beyond salvage but they did supply parts to repair others.

During period of severe unemployment in the 70's I sold my entire lab and when I started doing more computer work I had no need for RF test equipment.

In my humble opinion the first three items are a good VOM, a VTVM, and a decent signal generator.

I have a Triplett and a Heathkit VOM. For power supply work they both work just fine.

I have several versions of the Heathkit VTVM. The EICO VTVM is just as good. The problem I find with these being offered on eBay is that the probes are usually missing. But you can make probes. If you don't have the skill to make a VTVM probe you should probably not be trying to work with this stuff.

For a signal generator I have a Heathkit IG-102 and a Heathkit SG-8. They are both essentially the same, just different cases.

I do have much more than this, but these are the minimum you need to work on radios.

After watching this list and talking to Terry over the past few years I seem to think many of the problems are quality of the Kenwood PC boards. A skilled technician should be able to repair these boards. Once one is out of the unit I would just start by replacing all the electrolytic capacitors. In many cases you cannot measure the value of resistors in the circuit. You may have to lift one end of them.

It looks to me like the main problems encounters are with the connectors and relays.

I have a TS-520 I bought here locally a few years ago. It was demonstrated to me on a dummy load. The one problem it has is the carrier balance. You can get a good null on either LSB or USB but not on both. But in the three years I have had it I have only used it as a receiver.

I now have everything I need (EXCEPT SPACE) to set up a full hybrid station. I am going to work on that problem this year.

I would be willing to help anyone in the Puget Sound are solve hybrid problems.

Terry,

The kids don't see any need for ham radio anymore. They have their cell phones and internet message boards.

We have two radio clubs in the Seattle/Tacoma area. People join these clubs because of the 2M FM repeaters. The cost of a 2M FM transceiver less than $200. Modern SSB HF transceivers is much more.

Then there is the problem of HF antennas. HF antennas in an apartment environment is almost impossible. just ask me! Most new homes have HOA restictions that make a decent HF antenna difficult.

I suspect that the few young people the do find an interest in HF buy a boatanchor like the hybrids do so because the cost is lower than a new RICEBOX. But most of these boatanchors purchased on eBay have some kind of issues.

Somehow I get the feeling that the Kenwood hybrids have more problems than the Heathkit SB /HW units. For one thing I don't see the PCB/connector problems with the Heathkit units.

The Drakes have a completely different set of problems.

The other problem is most of these people do not understand analog electronics or electronics at all. They often cause more damage to the units they are trying to repair.

Wes:

I thought about approaching the schools and like you I have the time but not the budget. Very recently I was a little discouraged when had 18 year old nephew in the shack and gave him a demo including working a Russian station while he was here. He liked the service bench but when all done and we were outside looking up at my tri-bander on the tower he pulled out his cell phone and pointed at it and told me he still didnt understand why I went to all the bother!

I dont have any integration of computer other than do use my lap top and audio spectrum analyzer software for LSB/USB carrier adjust. I wish had SDR and IF connection and pan adapter to show him as an example of how it relates to his world. He is heading off to college and I encouraged him to check out the campus club station. Hope he does.

I will think about your approach and interested to here off list how it goes. Went to club meeting recently and saw 8 or 9 old guys like me and a couple guys maybe in 30s and two meters was the talk. No 16 year old kids there and no hybrids in sight.

Take Care
Terry K9TW

If you are saying the contacts on the switches are black that is OK. It's normal. Silver oxide is black but it still conducts. Get a can of DeOxit as a starter.

Do you have the manual? If not get one.

When mentioning “VTVM”, are you using the term colloquially or do you mean a real VTVM?

I have a Fluke 179 DMM that I use to measure everything that can be measured by a DMM. Also have a Fluke 85RF probe that I bought new but cheap on Ebay long after Fluke discontinued them. Why would I need a VTVM?

Does a real VTVM (that is – Vacuum Tube Volt Meter) do something that a modern DMM doesn’t do just as well?

I think he is trying to say that he bought an Eico 324 signal generator on e-Bay yesterday, and it's dirty. He wants to clean it up and doesn't know how.

To clean the contacts and moving parts, there are spray cleaners, usually labeled "contact cleaner" or "volume control cleaner."

And there are as many different opinions about which one works the best as there are Hams using them. Find one locally available and give it a squirt.

Simple mechanical scrubbing with a clean cloth and some of the spray cleaner will clear up things like edge connectors. Potentiometers should be sprayed and worked full-range while spraying. Likewise toggle switches or rotary switches. Open-plate capacitors (tuning capacitors) can be cleaned the same way.

I use "canned air" (nitrogen tank, much cheaper over the long haul) to blow out dust-bunnies and to dry the spray cleaner off of things once they're no longer corroded or dirty.

Another thing for connectors and any kind of contact that you can get to easily, such as the traces in a rotary switch, is a simple clean pencil eraser. I use one for commutator pads in electric motors, too. Just rub gently at the copper pads, and the gunk will come off. Clean it off of the eraser onto something, a piece of paper usually works.

Do I need to say "UNPLUGGED," here? Or is that enough of a given with this group? I suspect opinions on THAT differ as well....

Continue with spray cleaner and erasers and just plain scrubbing until the thing is tidy inside.

Yes a REAL VTVM does at least one thing better than a DMM.

When you are trying to find a peak or trying to peak a circuit an analog meter is better because it is easier to see the peak on the moving needle.

In most cases on these radios the accuracy of a DMM is not needed and a VOM or VTVM are satisfactory..

Hi Bob:

Interesting perspectives about why new folks are buying the hybrids and/or going with 2 meters. I had a new fellow visit the shack a year or so ago and he took a class conducted by a local club and they strongly recommended he buy two meter rig and if he bought a HF rig that first required accessory was an antenna tuner. I had hard time explaining to him why I had no tuner and when I did what kind of antenna it was.

One of the scariest things to me that I worry about all the time about giving advice to new Hybrid owners is these folks getting in the inside of these rigs with no appreciation for the safety risks or how to apply standard safe electrical work practices. Real chance to get hurt or worse. Maybe unfounded. I agree cant hope to maintain without modest test gear and understanding how to use it and knowing its limitations.

Nothing wrong with Heath level bench at all as we have discussed. Most if not all of us started with Heath, Knight, Eico. I still have some Heath test gear. I dont have laboratory RF bench. I am one step above Heath and only after raising 5 children and retiring. It was test gear or Corvettes and I got the Corvettes out of my system (70 LT-1 bumper car and 93 LT-1 both black beauties). Only memories now!

Probably the best upgrade you can do is in the RF Sig Gen area followed by RF millivolt meter. I upgraded from IG-102 to URM/25 and then HP-606 and finally now have a nice Wavetek 3002. A HP8640B or Wavetek 3002 gives you stable, accurate,calibrated output levels,and low level leakage required for accurate alignment and measurements.

The pieces I use the most include a Boonton 92E RF Millivolt meter, HP5334 Freq Counter, Wavetek 3002 RF sig gen, BK2712 DMM, and now a brand new Rigol DS1102E 100 mhz digital scope. Started many moons ago with RCA O-scope with 5 mhz BW and then built couple of Heath scopes, finally got a surplus 100mhz Lavoie Labs that took up half the bench. Then a Tek465 and then Tek475 and Tek475A. Still have the 475A but it needs some help. Still learning how to use this Digital scope. Jury is out.

I agree the hybrid boards are poor quality and the plating isnt good. Very easy to lift a foil and pull molex pins and have cracked trace at the pads. I upgraded to a Hakko 808 and man what a difference from solder sucker and solder wick. No comparison whatsoever especially for bandswitch removal and repair. Boards and connectors do present significant challenge. Certainly not the G10 quality.

I see boards that I will not have in any of my personal rigs.

I was hoping someone would reproduce them to todays standards. Would be a task to populate them, but I would be interested in buying sets for my rigs. Doubt it will ever happen.

Take Care
Terry K9TW

Thanks for that reply, Bob. Makes sense. Actually, I do have an old VOM that is rated at 50K ohms / volt, although it's transistorized, not a VTVM. Same idea and same "peak" benefits as a VTVM, though.

That said, I haven't used the old VOM in over a decade. I'm able to see the peaks easily on a digital meter, which I suppose is a side-effect of having grown up in a digital world.

Yes a REAL VTVM does at least one thing better than a DMM.

When you are trying to find a peak or trying to peak a circuit an analog meter is better because it is easier to see the peak on the moving needle.

In most cases on these radios the accuracy of a DMM is not needed and a VOM or VTVM are satisfactory..

When mentioning "VTVM", are you using the term colloquially or do you mean a real VTVM?

I have a Fluke 179 DMM that I use to measure everything that can be measured by a DMM. Also have a Fluke 85RF probe that I bought new but cheap on Ebay long after Fluke discontinued them. Why would I need a VTVM?

Does a real VTVM (that is – Vacuum Tube Volt Meter) do something that a modern DMM doesn't do just as well?

Away from the flaming,

Terry and I have talked privately many times in the past. I am jealous of the test lab he has.

But I also have a decent one and I know how to use all the equipment.

I don't approve of people with out knowledge and test equipment trying to repair these radios. If they really want to do it they need some basic test equipment. I find that most of my needs are filled by Heathkit test equipment. About 10 years ago I started rebuilding my lab off eBay. I did buy a couple pieces that were beyond salvage but they did supply parts to repair others.

During period of severe unemployment in the 70's I sold my entire lab and when I started doing more computer work I had no need for RF test equipment.

In my humble opinion the first three items are a good VOM, a VTVM, and a decent signal generator.

I have a Triplett and a Heathkit VOM. For power supply work they both work just fine.

I have several versions of the Heathkit VTVM. The EICO VTVM is just as good. The problem I find with these being offered on eBay is that the probes are usually missing. But you can make probes. If you don't have the skill to make a VTVM probe you should probably not be trying to work with this stuff.

For a signal generator I have a Heathkit IG-102 and a Heathkit SG-8. They are both essentially the same, just different cases.

Hi Terry,

Since I am now 79 and limited to what I can do on Social Security I am limited to what I can spend on test equipment now.

For what I do I can use an external attenuator with the Heath signal generators. The one item I really do want is a RF milivoltmeter.

Would it be practical to do the artworks(maybe just copy the Kenwood board) and get someone to produce the bare boards. Then let people buy the boards and assemble them themselves?

What kind of quality are the Farr Circuits PC boards?

In watching the Kenwood items on eBay I have been seeing lots of Kenwood items being parted out. The same has been true of Heathkit ham radios.

Subject: Re: [TS-520_820_530_830]Moving Forward (Was FLAMED)

Hi Bob:

Interesting perspectives about why new folks are buying the hybrids and/or going with 2 meters. I had a new fellow visit the shack a year or so ago and he took a class conducted by a local club and they strongly recommended he buy two meter rig and if he bought a HF rig that first required accessory was an antenna tuner. I had hard time explaining to him why I had no tuner and when I did what kind of antenna it was.

One of the scariest things to me that I worry about all the time about giving advice to new Hybrid owners is these folks getting in the inside of these rigs with no appreciation for the safety risks or how to apply standard safe electrical work practices. Real chance to get hurt or worse. Maybe unfounded. I agree cant hope to maintain without modest test gear and understanding how to use it and knowing its limitations.

Nothing wrong with Heath level bench at all as we have discussed. Most if not all of us started with Heath, Knight, Eico. I still have some Heath test gear. I dont have laboratory RF bench. I am one step above Heath and only after raising 5 children and retiring. It was test gear or Corvettes and I got the Corvettes out of my system (70 LT-1 bumper car and 93 LT-1 both black beauties). Only memories now!

Probably the best upgrade you can do is in the RF Sig Gen area followed by RF millivolt meter. I upgraded from IG-102 to URM/25 and then HP-606 and finally now have a nice Wavetek

3002. A HP8640B or Wavetek 3002 gives you stable, accurate,calibrated output levels,and low level leakage required for accurate alignment and measurements.

The pieces I use the most include a Boonton 92E RF Millivolt meter, HP5334 Freq Counter, Wavetek 3002 RF sig gen, BK2712 DMM, and now a brand new Rigol DS1102E 100 mhz digital scope. Started many moons ago with RCA O-scope with 5 mhz BW and then built couple of Heath scopes, finally got a surplus 100mhz Lavoie Labs that took up half the bench. Then a Tek465 and then Tek475 and Tek475A. Still have the 475A but it needs some help. Still learning how to use this Digital scope. Jury is out.

I agree the hybrid boards are poor quality and the plating isnt good. Very easy to lift a foil and pull molex pins and have cracked trace at the pads. I upgraded to a Hakko 808 and man what a difference from solder sucker and solder wick. No comparison whatsoever especially for bandswitch removal and repair. Boards and connectors do present significant challenge. Certainly not the G10 quality.

I see boards that I will not have in any of my personal rigs.

I was hoping someone would reproduce them to todays standards. Would be a task to populate them, but I would be interested in buying sets for my rigs. Doubt it will ever happen.

Take Care
Terry K9TW

Topic: 42351 Message: 42360

Analog VTVM meter movements are much better than DVM changing digits when performing peak alignment steps. Don't get me wrong, DVMs do have a place on the work bench. They are very good when measuring resistances, AC and DC voltages. But for alignment where I need to see how the adjustment is going, I will use a VTVM every time.

Like Bob, I have simple VTVMs from Heathkit and Eico. Most have transformers with secondary AC voltages of 120VAC at 20ma or so that's fed to a half wave rectifier and 6.3VACat 500ma or so for filaments. Most Heathkit VTVMs are basically the same, excluding the solid state VTVM, except for differences in the color scheme and probe design. Probes are not difficult to make if the meter doesn't come with them. Schematics are pretty much all one need's to fix a broken VTVM.

Not all DVMs, at least the one I have doesn't have any adjustments other than the voltage, current, and resistance switch, do not have adjustments to zero the display, especially on low resistance scale. The analog VTVMs have a front panel meter zero control.

I use the same siggen Bob uses, IG-102 but I connect a frequency counter in parallel with the generator's output using a BNC "T" connector. I also replaced the screw on connectors with female BNCs which make it much easier to connect different devices and probes to the generator.

I would add to Bob's bench collection, a frequency counter and a scope. The frequency counter is a good item to have especially when dealing with oscillators. I use a Synometer VC-2000. This counter will measure frequency from 10hz up to 2.5Ghz plus it has a simple crystal oscillator test feature where a crystal can be plugged into the front and the counter displays the crystal's frequency. This feature will only display the "Fundamental" frequency. Fundamental frequencies are typically frequencies 20Mhz and below. Unfortunately my scope has an upper limit of 20Mhz so it's not good for those hybrid measurements that require a 100Mhz scope.

Learning how to use test equipment is very easy. You don't have to have a Phd in electrical engineering and have spent many months in space on the space shuttle to learn how to use basic test gear.

Also, as I remember, a "real VTVM" came with, or has available probes designed to handle AC,DC, and RF High Voltage, with high impedance. Gosh, I remember the days when "HVAC" stood for High Voltage Alt. Current, and NOT Heating, Ventilation, and Air Conditioning!!! I am truly a relic !!

Seriously, I think it's possible to do serious damage to yourself or your test equipment playing around in The Big Leagues of Power, unless you know for certain that the instrument AND test leads can handle High Power, including maybe RF if you go past the power supply, with high impedance. so as not to load down RF circuits.

At least, that's what I remember being taught

Another "plus" of a REAL VTVM is that the DC probe has a 1M resistor at the probe tip. This resistor decouples the probe cable from the circuit and significantly reduces the load on an oscillator circuit. A DMM probe/cable can load down an oscillator and pull it off frequency, reduce its output, and/or cause it to stop working.

42363. VTVM vs DMM

What he said plus one other thing. A good VTVM generally will have a lesser loading effect on the circuit under test.

This is a function of input REACTANCE (not just input resistance), I am pretty sure.

If you check the same RF circuit with a VTVM and a DMM the VTVM will measure a higher voltage in every case I've done this comparison. Less load on the circuit equals greater -accuracy-.

Knowing the difference between "precision" and "accuracy" is key.

Load down, and de-tune. The wrong kind of test equipment load can make an oscillator stop, and an amplifier start.... More of a problem in the higher frequencies, in my (military) experience. Accuracy vs. precision again...

Also, RF burns are the WORST. Serious pain.

Even little ones. Cooked fingers, ye-ouch!!

Now -this- is something I might be able to get done. Which radio (in your guesstimation) would be the one most likely to generate a quantity greater than say, 50 people, willing to do this sort of thing?

I think there wouldn't be a problem with the copyright for a non-profit break-even quantity of something they don't have any interest in supplying ever again.

(Especially if we hit Kenwood up for permission, though it probably isn't needed. I'll ask my lawyer a question about that if this goes any further.)

I know the artwork/layout can be recreated (I've done it with just GIMP, an HP LJ4 printer, and a clothes iron).

There are small-run jobbers that can do this sort of production run, lots of them are in folk's garages or a storage shed in the back yard. My little brother has a CNC laser etching business he runs in his garage. He can put a picture or words on about anything with that laser, so long as you supply a picture or the text.

But those sorts of small shops are capable of small quantity runs (given the artwork) of very high quality circuit boards. Cost per board wouldn't be too great, though they wouldn't be exactly cheap either. Say, ballpark, ten to twenty dollars per, depending on size and complexity? That's a GUESS, please don't hold me to it.

We could even include a few 'tweaks' just for fun, if you like....

From: Bob Macklin
Topic: 42351 Message: 42366

I do have several scopes. The best for me has been a Heathkit IO-4235. 35MHz. I like it because I have the full assembly manual. When I bought it (ebay of course) it had a LV power supply problem. It was easy to fix. I just had to replace two LV electrolytic filter capacitors. The second problem occurred after I had been using this scope for more than a year. One of the capacitors in the timebase failed. It took a couple days to repair. The first problem was finding it.

I also have a Korean made 35MHz scope I purchased new about 25 years ago. In it one of the LV voltage regulators failed. I don't have the manual for this scope but I do have the manual for the 20MHz version made by the same company. The power supply was close enough for me to find the bad chip.

I also have a 250MHz Heathkit counter. I have done the same. Connecting it to the output of the IG-102. I have been planning to put a RCA connector on the back of the IG-102 so the counter would not be affected by the attenuator. You also need to remember to turn off the modulation when reading the counter.

I tried using the counter to set the LO in a couple tube type receivers I found the counter or the scope would add enough capacacitance to the LO to effect the tuning. I need to try and find a low impedance point (cathode) on these oscillators for the measurement but they are often difficult to get to.

But my main point is that people that want to work on old radios need to have at least the three items I initially mentioned.

I did consider a Tek 4XX series scope. I worked with them for many years. I have the manuals on several. I deiced on the Heathkit scope because I can usually fix them. I'm not sure ant my age I want to try working inside a Tek 4XX scope.

Analog VTVM meter movements are much better than DVM changing digits
when performing peak alignment steps. Don't get me wrong, DVMs do have a
place on the work bench. They are very good when measuring resistances,
AC and DC voltages. But for alignment where I need to see how the
adjustment is going, I will use a VTVM every time.

Like Bob, I have simple VTVMs from Heathkit and Eico. Most have
transformers with secondary AC voltages of 120VAC at 20ma or so that's

fed to a half wave rectifier and 6.3VACat 500ma or so for filaments. Most Heathkit VTVMs are basically the same, excluding the solid state VTVM, except for differences in the color scheme and probe design. Probes are not difficult to make if the meter doesn't come with them. Schematics are pretty much all one need's to fix a broken VTVM.

Not all DVMs, at least the one I have doesn't have any adjustments other than the voltage, current, and resistance switch, do not have adjustments to zero the display, especially on low resistance scale. The analog VTVMs have a front panel meter zero control.

I use the same siggen Bob uses, IG-102 but I connect a frequency counter in parallel with the generator's output using a BNC "T" connector. I also replaced the screw on connectors with female BNCs which make it much easier to connect different devices and probes to the generator.

I would add to Bob's bench collection, a frequency counter and a scope. The frequency counter is a good item to have especially when dealing with oscillators. I use a Synometer VC-2000. This counter will measure frequency from 10hz up to 2.5Ghz plus it has a simple crystal oscillator test feature where a crystal can be plugged into the front and the counter displays the crystal's frequency. This feature will only display the "Fundamental" frequency. Fundamental frequencies are typically frequencies 20Mhz and below. Unfortunately my scope has an upper limit of 20Mhz so it's not good for those hybrid measurements that require a 100Mhz scope.

Learning how to use test equipment is very easy. You don't have to have a Phd in electrical engineering and have spent many months in space on the space shuttle to learn how to use basic test gear.

Ten or twenty bucks to save a radio from being scrap is really a small cost. Much less than buying a new radio.

Newer radios have ICs that are not replaceable. That is another problem.

But one thing to consider is the relays used in the hybrids. Would it be advisable to design the replacement PCBs to use modern (current production) relays?

Should we feel that the people repairing these radio could assemble the replacement PCBs themselves. We could supply a Mouser or DigiKey parts list.

Is there a particular problem board?

Yes. That would be a good start on about any piece of old kit.
Replacing the electrolytics that may have dried out or failed in other
ways couldn't be a bad way to begin.

42371. Re: [TS-520_820_530_830] VTVM vs DMM

Thanks for all the replies.

I never considered that a DMM might have enough reactance to affect readings. My DMM (Fluke 179) is a “true RMS” meter, so I would expect that it has some circuitry that removes the reactive component from measurements – but I’m not certain. Maybe others can comment on this.

> VOM or VTVM are satisfactory..

What he said plus one other thing. A good VTVM generally will have a
lesser loading effect on the circuit under test.

This is a function of input REACTANCE (not just input resistance), I am
pretty sure.

If you check the same RF circuit with a VTVM and a DMM the VTVM will
measure a higher voltage in every case I've done this comparison. Less
load on the circuit equals greater -accuracy-.

Knowing the difference between "precision" and "accuracy" is key.

I think he is trying to say that he bought an Eico 324 signal generator on e-Bay yesterday, and it's dirty. He wants to clean it up and doesn't know how.

To clean the contacts and moving parts, there are spray cleaners, usually labeled "contact cleaner" or "volume control cleaner."

And there are as many different opinions about which one works the best as there are Hams using them. Find one locally available and give it a squirt.

Simple mechanical scrubbing with a clean cloth and some of the spray cleaner will clear up things like edge connectors. Potentiometers should be sprayed and worked full-range while spraying. Likewise toggle switches or rotary switches. Open-plate capacitors (tuning capacitors) can be cleaned the same way.

I use "canned air" (nitrogen tank, much cheaper over the long haul) to blow out dust-bunnies and to dry the spray cleaner off of things once they're no longer corroded or dirty.

Another thing for connectors and any kind of contact that you can get to easily, such as the traces in a rotary switch, is a simple clean pencil eraser. I use one for commutator pads in electric motors, too. Just rub gently at the copper pads, and the gunk will come off. Clean it off of the eraser onto something, a piece of paper usually works.

Do I need to say "UNPLUGGED," here? Or is that enough of a given with this group? I suspect opinions on THAT differ as well....

Continue with spray cleaner and erasers and just plain scrubbing until the thing is tidy inside.

Bob: I understand fixed income. Blowing thru my retirement and if live long enough will be limited to SS. Hopefully the kids will take me in!

I have never seen a FAR produced PC board. On his site he says he specializes in one off ham projects. He states the boards are made of G10 with 1oz copper traces that are tinned. That alone is better than our old phenolic boards in the hybrids.

Not smart enough to know how the art work could be produced.

Well yes must have external step attenuator, but still have problem of knowing precisely what your base level from the IG-102 is. Cant assume what it is. Can measure it fairly close with an O-scope of sufficient bandwidth.

I use to drive a commercial receiver with my IG-102 and assume the S-meter in it was calibrated accurately and then use attenuator from what ever S-meter level I used. Problem is most S-meters are not linear. So for example I would drive the receiver for an S-9 reading and assume that the receiver had been calibrated for 50uv = S-9. Then could use step attenuator to get "accurate" lower levels.

If it was just for my personal radios I would not need a good RF signal generator, but when you charge people to perform full factory alignments on their hybrids you owe it to them not to skip any steps and to return the rig as close to factory spec as you can. No guessing allowed there.

Before I would send any radio to anyone who advertises Hybrid repair I would want to see a list of their test gear and ask them a couple of questions like how they check the bandpass filter alignment, how they set the VBT oscillator, etc.

This isnt rocket science, but it has to be more than set by ear and just good enough in my opinion.

Take Care
Terry K9TW

>
> Hi Bob:
>
> Interesting perspectives about why new folks are buying the hybrids and/or going with 2 meters. I had a new fellow visit the shack a year or so ago and he took a class conducted by a local club and they strongly recommended he buy two meter rig and if he bought a HF rig that first required accessory was an antenna tuner. I had hard time explaining to him why I had no tuner and when I did what kind of antenna it was.
>
> One of the scariest things to me that I worry about all the time about giving advice to new Hybrid owners is these folks getting in the inside of these rigs with no appreciation for the safety risks or how to apply standard safe electrical work practices. Real chance to get hurt or worse. Maybe unfounded. I agree cant hope to maintain without modest test gear and understanding how to use it and knowing its limitations.
>
> Nothing wrong with Heath level bench at all as we have discussed. Most if not all of us started with Heath, Knight, Eico. I still have some Heath test gear. I dont have laboratory RF bench. I am one step above Heath and only after raising 5 children and retiring. It was test gear or Corvettes and I got the Corvettes out of my system (70 LT-1 bumper car and 93 LT-1 both black beauties). Only memories now!
>
> Probably the best upgrade you can do is in the RF Sig Gen area followed by RF millivolt meter. I upgraded from IG-102 to URM/25 and then HP-606 and finally now have a nice Wavetek 3002. A HP8640B or Wavetek 3002 gives you stable, accurate,calibrated output levels,and low level leakage required for accurate alignment and measurements.
>
> The pieces I use the most include a Boonton 92E RF Millivolt meter, HP5334 Freq Counter, Wavetek 3002 RF sig gen, BK2712 DMM, and now a brand new Rigol DS1102E 100 mhz digital scope. Started many moons ago with RCA O-scope with 5 mhz BW and then built couple of Heath scopes, finally got a surplus 100mhz Lavoie Labs that took up half the bench. Then a Tek465 and then Tek475 and Tek475A. Still have the 475A but it needs some help. Still learning how to use this Digital scope. Jury is out.
>

> I agree the hybrid boards are poor quality and the plating isnt good. Very easy to lift a foil and pull molex pins and have cracked trace at the pads. I upgraded to a Hakko 808 and man what a difference from solder sucker and solder wick. No comparison whatsoever especially for bandswitch removal and repair. Boards and connectors do present significant challenge. Certainly not the G10 quality.
>

The start by putting the scope on the HV power supply and looking at the ripple. There should not be very much if any.

Go here and get the complete manual:
http://bama.edebris.com/manuals/eico/324/

Jerry,

You have an RF generator from ebay but what else are you trying to say?

IF board is plugged and unplugged the most to change and sell filters. I see more jumpers and solder jobs that look like open flame and acid core solder on the IF boards. Some real abortions.

RF bandswitch boards would sell to just about everyone I would think. The silver ink repair in my opinion is not as good as the small jumper wire repair. Having to do neither would be nice.

If I could buy factory new RF boards and IF boards for my two TS-830s without mortgaging the house I would be first in line.

Okay, no problem.

The manual and schematic, including the assembly manual (listed as "CONST" in the link below) which I recommend you download, can be found at the following link:

http://bama.edebris.com/manuals/eico/

I agree, as others have said, replace the electrolytic caps first. There's one multi-section capacitor with two 20ufd 150VDC caps. You can purchase from Mouser (www.mouser.com) new 22ufd 160VDC axial lead replacement caps. You can either restuff the original cap's body or remove the old cap and install new axial lead caps tie wrapped together. You will need some heat schrink tubing over the positive leads to ensure they don't short to the chassis. The original cap is mounted to the chassis with a strap Simply look where the positive leads connect, make a note or better yet take a picture of the connections, then remove the old cap and install the new caps.

Next, you should clean all the switches and pots with contact cleaner. I use DeoXit D5 on switch and DeoXit F5 fader cleaner and lub on pots. I also recommend purchasing a few cans of canned air, you can find it at Walmart's stereo/TV/DVD section. Once you have cleaned the switches and pots, use generous amounts of canned air to remove any/all cleaner residue. Adhere to the cleaner's warning on the can.

Take some time and read the manual so you will have an idea of how the generator works, how to use the generator etc.

You beat me to it Bob.

Jerry, if you do not have the assembly manual for the 324 then download it. The assembly manual will have pictorials that show how the generator is constructed, with part numbers, values etc.

Visually inspect the tubes. If either one of the tubes show "white" coating on the inside, throw them away and order a replacement. I've run into this when purchasing test gear on eBay. Check to ensure the filaments are lit. If the filament is open then the tube is bad and needs replaced.

If Far could do these two boards that would be a good start.

I assume that someone that knew what he was doing could assemble and test these boards before they were put in a radio.

I'll contact Far and see what he says.

To add to the good advise you have already received. The Eico 324 was available in kit form and factory assembled.

For any LC type signal generator of the Heath,Knight, Eico vintage I would suggest the following:
1. As already recommended the manual and schematic is a must.
2. Do a good visual inspection. Look for signs of leakage at the filter cap vents. Personally I would just recap it. Dont worry about original configuration. You are not restoring to original. Just need a functional generator. Look for wires not soldered or broken leads. Look for signs of overheated components.
3. Use contact cleaner and canned air on all the switches and pots.
4. Plug and unplug and re-seat the two tubes in their sockets to wipe the pins. I would buy NOS tubes and replace them.
5. This unit has a selenium rectifier in it. I would replace it with silicon rectifier. Cant just swap one for one, but if you decide can tell you how to figure series resistor.
6. Tighten all the terminal strip mounting hardware. Often the kit built units the builder failed to tighten the phenolic terminal strip hardware and you may have bad ground connections.
7. If it powers on take tube dc voltages and compare to schematic.
8. Best to look at output with Freq Counter to see if it is aligned and tracks reasonably well.

Did it come with original test lead? These can be in bad shape. I would change out to front panel connector to BNC type.

Yes single sided in your TS-520. Now we do have boards with plated thru holes but that is another story. Some 820 owners can speak up here about what boards they would like to see. I dont believe FAR does any double sided boards?

Terry

> unplugged is good.

Just use more cleaning spray. Some light work with a medium-stiff brush to remove any caked-on dirt/dust. CAREFULLY. De-Oxit 5 (if I remember a-right) has a lubricant in it, so just use that. I DON'T RECOMMEND petroleum jelly, it tends to get into places it oughtn't.

Any of the control-linkage sprays or lubes for electronics will loosen the knobs, if the shafts aren't kinked or bent. No WD-40, either, by the way. Just haven't had any good luck with that stuff for anything electronic. Works fine of cabinet hinges, though...

If you can, search the internet (GOOGLE.COM or I use IXQUICK.COM) for

eico model 324 signal generator schematic manual

You should be able to turn up a PDF file manual somewhere. (I'm being lazy, didn't search it myself.) You can copy and paste that line above to the search engine page.

See what comes up, but DO NOT pay money for it on-line. Check here FIRST, most of those "We'll sell you a manual," places add "SUCKER!" when you hang up the phone.

This is BASIC cleaning of equipment. It more or less applies to ANYTHING, old, new, or in-between:

Check the circuit boards for obvious damage. Burned spots on the phenolic side, blackened components, burned or missing traces on the copper side, if there are circuit boards and it's not all point-to-point. (I don't remember if I've ever been under the hood of a 324, so I don't have any idea of the construction methods.) Cracked or lifted traces on circuit boards. Cold solder joints. Cracking insulation on point-to-point wiring. Loose or corroded connectors.

Also look for popped or bulging capacitors, leaking electrolytic compound, any sort of crystallized powdery residue particularly on or underneath capacitors, and particularly electrolytic capacitors.

Excess flux on solder joints, that will leave a whitish or resiny coating on things. Clean it off with flux remover (best) or isopropyl (rubbing) alcohol (cheapest) and dry THOROUGHLY.

Check coils for mashed, displaced, or broken windings. You have to lift one end of a coil (and a resistor, and a diode, and about anything else, if it's a 2-lead device) and check it for simple continuity. Won't tell you if it's still the right electrical size, but will tell you if the windings are broken.

Anyone else here still use a grid dipper?? Or am I REALLY a dinosaur??

If you take ANYTHING apart (even the CASE if it's a tricky disassembly) TAKE NOTES, or a digital snapshot of the thing as it comes apart (BOTH NOTES AND PIX), so you know how it goes back together.

Keep the screws in something that you're not going to tip over every time you reach for a tool and spread ballistically all over the room.

If possible, and if they won't be in the way of getting the next bit out, PUT THE SCREWS BACK IN THE HOLES THEY CAME OUT OF after the sub-assembly or component has been taken off the chassis or whatever. That way, you know for sure where the screw came from.

Replace and repair as you find problems. Once the obvious stuff is taken care of, then you dive into the schematic and start tracing signals and verifying biases, and making sure that power supplies are supplying power, and that kind of stuff.

The Mark I Eyeball is your best diagnostic tool when you begin with an old piece of gear.

Good Luck.

> set the VBT oscillator, etc.

Preaching to the choir here, man. I wish everyone who was looking for paid repair work on the internet would apply due diligence and check out the bona fides of the results of their google searches. Just taking the first one that pops up in the list might not be a good enough way to get a top-notch job done on a treasured piece of gear.

The good ones will provide their set-up and a clear picture of their procedures without even asking. Check some of the ones referenced here by several people on this list in the past; hybridrestore and K4EAA's repair site mainly.

I have not personally used either, but have had a conversation via email about the 520SE I am trying to fix. CANNOT say definitively from personal experience if either are good or bad, but only because I have never used them.

(Going by a couple of brief emails, their web sites, and their on-line reputations, I'd trust either of these two to do anything at all with a hybrid. If I could afford to, one of those two would get this job. There are assuredly others, but these two sites pop up -constantly- with high recommendations.)

Jerry,

The manuals on BAMA are really USER manuals. No assembly information.

I have the assembly manual but I need your email address to send it to you.

Hello Terry,

I’m responding to you email for the first time since I didn’t reply to your original email for good reasons. I am a bit concern that you assume that my feelings were hurt. I’m sure when you sent you email you assume many things. First of all, I spend 20yrs in the U.S. Marine Corps proudly severing my Country.
I severed from 1972-1992 and fought in two wars dodging bullets and IEDs while having to witness the killing of Marines in my unit. I wonder your activity during that time that made you a big man as to call someone “little sissy”. I retired from the Marines and continued to work for the government in the Department of Treasury and recently took an early retirement. I’ve been married for 39yrs to the same woman and a father of 3 grown adults, with 5 grandchildren. The point is this you knew nothing about me and the sad thing is you ranted like a child, this is the reason I didn’t reply. My point is if a 19yrs old person ask this question and received your rant it may have discouraged them. Maybe you need to change your mind set it doesn't matter what other group do, it's what we do in this group that counts. If you feel like ranting don’t answer the email the earth will continue to turn and maybe they’ll ready their manual. Remember that
Ham Radio is not just about tubes it also about people. I hope this helps you and thanks again for all the good Info you give. I hope this answered your question about my feeling.

Note: I did read the manual and knew what the plate current was for the
TS-530, but wanted to know if 265mA was the setting used by current owners. Terry you know from your own experience and others in the group that sometimes what the manual states and what people actually experience with their rigs can be different. Terry I’m very sorry I didn’t word the question to your liking. I’ll do better next time.

If you consider this getting "flamed" you are going to get your feelings hurt daily in this old life.

This is a technical hobby that use to have high entry level requirements. If you dont have the bug and a passion for learning you are in wrong hobby and certainly have purchased the wrong radio. Yahoo forums by design provide a place for people with parochial interest.

If the charter of this forum is to serve as a "Help Desk" for the general public or appliance operators who are staring at a electronic black box trying to figure out how to turn it on with the manual on the floor then I dont care to be a member of that club.

If you cant open your TS-530 instruction manual and read the transmitter section on how to tune and load it including the maximum full load current you should sell your hybrid. If you read the instructions and have some questions about what you read that is an entirely different matter and what this forum is for.

My idea of this forum is the members share a common bond. A love of Kenwood Hybrids and desire to keep them on the air. They are above average intelligence and they come here because they want to learn how to operate the rig properly, how to maintain it, how to troubleshoot and repair it, and most importantly learn how it works. You wont accomplish any of that without some effort.

To accomplish that requires something between the ears and a willingness to do a little work. There can be no real learning if the student has no aptitude, no interest, and no work ethic.

If that is not what this forum is about then I am sorry. My mistake.
I am not interested in sitting on a "Help Desk" for the general public or appliance operators who just want an answer.

Strongly suggest you sell your Kenwood hybrid and buy a no tune solid state rig and have fun with it. That way not much chance of getting your feelings hurt by a teacher who has some expectations for you. If it breaks throw it away and get a new one.

Man it is sad what has happened to this hobby. I would love it if I could find just one young person to mentor who was a voracious reader, had a questioning attitude, had a gleam in his eye and fire in the belly, and would not go crying down the hall like a little sissy when he was pressed to do a little work. I guess that was a very different time.

> 1. Where did 225 ma come from? Ken Kempski K4EAA in his FAQ section suggests that 800v X 225 ma = 180 watt dc input power and it is pointless to exceed this level as it wont make perceptable difference on the receive end of a transmission and loading to this level (assuming proper loading technique) can extend final tube life. Without saying it Ken was obviously speaking about TS-530 and TS-830 rigs as they are the only two models with 180 watts dc input ratings. He would not recommend loading to 180 watts dc input power on a radio designed for 160 watts dc input power.
>
> 2. Why are the early rigs rated at 160 watts dc input and later rigs at 180 watts dc input? I Do Not Know With 100% Certainty. What I Believe is that it is due to the switch from S2001A finals to 6146B finals. I Believe 6146B tubes have higher Plate dissipation ratings. I have never seen a S2001A Data Sheet and do not know there plate dissipation or any of there ICAS max ratings. If anyone has one please send to Gordon N6WK so he can post on his site.
>
> 3. Is there any difference in the HV power supply capacities? No apparent or published differences that I have seen. Maybe we can ask Bob Mansker to hack transformers out of these rigs and weigh them to see if difference in copper and iron? Transformer weight roughly corresponds to KVA capacity.
>
> 4. Sorry about my frustration. This is suppose to be a thinking mans hobby. You have to be able to read and read with comprehension. Lacking this ability you are in trouble. Very easy to just ask and expect an instant answer with out doing any modest amount of homework. Maybe it is a age and cultural thing? I prefer to help those who are willing to help themselves.
>
> 5. Lets stop putting wrong information out on this forum. Easy to just "Parrot" what you have heard. This is how tribal myths perpetuate. If you are going to respond do so as an "expert" or do so by qualifying your response. I will try to remember to preface my remarks by telling you what I "know" first and then what I "believe". Can be a big difference between those.

Subject: Re: [TS-520_820_530_830] Re: FLAMED

Hello Terry,

I’m responding to you email for the first time since I didn’t reply to your original email for good reasons. I am a bit concern that you assume that my feelings were hurt. I’m sure when you sent you email you assume many things. First of all, I spend 20yrs in the U.S. Marine Corps proudly severing my Country.
I severed from 1972-1992 and fought in two wars dodging bullets and IEDs while having to witness the killing of Marines in my unit. I wonder your activity during that time that made you a big man as to call someone “little sissy”. I retired from the Marines and continued to work for the government in the Department of Treasury and recently took an early retirement. I’ve been married for 39yrs to the same woman and a father of 3 grown adults, with 5 grandchildren. The point is this you knew nothing about me and the sad thing is you ranted like a child, this is the reason I didn’t reply. My point is if a 19yrs old person ask this question and received your rant it may have discouraged them. Maybe you need to change your mind set. If you feel like ranting don’t answer the email the earth will continue to turn and maybe they’ll ready their manual. Remember that Ham Radio is not just about tubes it also about people. I hope this helps you
and thanks again for all the good Info you give. I hope this answered your question about my feeling.

If you consider this getting "flamed" you are going to get your feelings hurt daily in this old life.

This is a technical hobby that use to have high entry level requirements. If you dont have the bug and a passion for learning you are in wrong hobby and certainly have purchased the wrong radio. Yahoo forums by design provide a place for people with parochial interest.

If the charter of this forum is to serve as a "Help Desk" for the general public or appliance operators who are staring at a electronic black box trying to figure out how to turn it on with the manual on the floor then I dont care to be a member of that club.

If you cant open your TS-530 instruction manual and read the transmitter section on how to tune and load it including the maximum full load current you should sell your hybrid. If you read the instructions and have some questions about what you read that is an entirely different matter and what this forum is for.

My idea of this forum is the members share a common bond. A love of Kenwood Hybrids and desire to keep them on the air. They are above average intelligence and they come here because they want to learn how to operate the rig properly, how to maintain it, how to troubleshoot and repair it, and most importantly learn how it works. You wont accomplish any of that without some effort.

To accomplish that requires something between the ears and a willingness to do a little work. There can be no real learning if the student has no aptitude, no interest, and no work ethic.

If that is not what this forum is about then I am sorry. My mistake.
I am not interested in sitting on a "Help Desk" for the general public or appliance operators who just want an answer.

Strongly suggest you sell your Kenwood hybrid and buy a no tune solid state rig and have fun with it. That way not much chance of getting your feelings hurt by a teacher who has some expectations for you. If it breaks throw it away and get a new one.

Man it is sad what has happened to this hobby. I would love it if I could find just one young person to mentor who was a voracious reader, had a questioning attitude, had a gleam in his eye and fire in the belly, and would not go crying down the hall like a little sissy when he was pressed to do a little work. I guess that was a very different time.

>
> 1. Where did 225 ma come from? Ken Kempski K4EAA in his FAQ section suggests that 800v X 225 ma = 180 watt dc input power and it is pointless to exceed this level as it wont make perceptable difference on the receive end of a transmission and loading to this level (assuming proper loading technique) can extend final tube life. Without saying it Ken was obviously speaking about TS-530 and TS-830 rigs as they are the only two models with 180 watts dc input ratings. He would not recommend loading to 180 watts dc input power on a radio designed for 160 watts dc input power.
>
> 2. Why are the early rigs rated at 160 watts dc input and later rigs at 180 watts dc input? I Do Not Know With 100% Certainty. 42390. Re: VTVM vs DMM

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-29 22:43:52 UTC
From: Terry Wagoner
Topic: 42351 Message: 42390

You do not have to worry about any "reactive component" at input of your Fluke.

People have already pretty much described why you want analog VTVM for tuning, peaking, nulling. If you ever want to do any FM discriminator work you would appreciate the large zero center analog meter. Cant use a DMM to check inter-stage capacitor leakage. The DMM will miss the charge kick. Also the analog VTVM can be placed across 8 ohm dummy load at speaker and measure the audio frequency voltage (a service manual test)as they have AF ac ranges of approx 15khz to 20khz. Most DMMs fall off at 1 khz ac voltage max.

Lastly, the ability to look up from the rig with your hands in it and at a glance see what you have is better than watching and waiting on your DMM. Experienced bench tech appreciates this ability. Part of the reason digital watches never really took off and replaced analog.

Wait a minute I have a bar graph on mine to see nulls and peaks. Yes but still not same as analog meter movement. Analog is continuous and your bar graph is being updated at 20 to 40 times per second if you have a good DMM.

In addition to being better for peaking Het Osc, carrier suppression, and neutralizing the high input impedance of the VTVM is a must for AGC and ALC bus work and Oscillator work as the others have pointed out.

Problem is that not all DMMs are true 10 meg ohm and/or not on all ranges. Many cheaper DMMs are designed for home and auto use and for electricians and not for radio electronics.

An electrician does not want a high Z meter. He is usually more interested in detecting the presence of voltage and proving it is not there before he installs safety grounds or bare hand touches. If he uses a high-Z DMM to check voltage in a distribution panel where feed breaker has been opened he may still read voltage. This voltage is ghost or phantom voltage due to the cables running in close proximity in the duct or raceway. The long runs results in inductive and capacitive coupling from an energized conductor to the de-energized one. He cannot ignore this voltage. To do so can result in a flash or electrocution. So he wants a DMM designed for an electrician. When it reads voltage that voltage is really there. When there is this phantom voltage present the low-Z input of the DMM will pull down this voltage and not display it and present this problem for him. Many DMMs that you see at Lowes or Home Depot are designed for electricians and not radio electronics.

Fluke among others make DMMs with certain ranges that are low Z by design just for industrial electricians.

Lesson is you need to read the specs on any DMM you intend to purchase. Some of the worst ones I have measured are the Harbor Freight $9.95 meters and some of the Sears meters. The Harbor Freights measure around 900k ohm input making them not useable for our Kenwood work beyond power supply measurements. As previously noted we cannot use a low Z DMM. It will pull or shut down our oscillators and will peg the S-meter and shut down the receiver AGC control bus and pull down the ALC bus to no indication.

If you already have a DMM you can test it by:
1. RF gain full CW
2. Rig on dummy load
3. AF gain at comfortable listening level
4. Locate your AGC bus connection at the IF board or RF board molex connectors. Connect your DMM and try to measure this voltage (voltage should be same as you have set your RF-1 at AVR board typically around 3.3 to 3.6vdc).
5. Anything less than 10 meg input will drive the S-meter up scale and drive the receiver gain down. Even with a 10 meg meter you will not be able to accurately measure the AGC bus voltage. The Harbor Freight special I mentioned will peg the S-meter and shut down your receiver.

Summary:
1. If have no meter buy a 11 meg analog VTVM and single diode and 3 diode rf probe. With this meter and probes you can make every AC, DC and RF voltage reading in the radio including all required and listed in the service manual.

2. A 10 meg FET based analog meter may be ok as long as the input Z is not range dependent. Some will be OK and others can go as low as 2 megs on some ranges.

3. There is a place for a DMM on Hybrid bench as Mike and others note. Great for power supply measurements, transistor CBE, FET DSG, and resistance readings.

4. If you are going to buy a DMM go on line and read specs. Pay attention to the input Z on all ranges and also look at current reading burden. Not a function you will use a lot, but some have horrible burden and cannot accurately read DC ma levels. Can need this for power supply troubleshooting.

5. Buy as much speed and resolution as you can afford in your DMM. Dont confuse resolution with accuracy. I have a 40,000 count true RMS and it is sure nice to be able to hand pick resistors like a 2.7k resistor at 2699.85 ohms. A must for picking meter multipliers.

Lastly, if after you do the AGC bus test with your DMM and are interested in measuring the input Z of your DMM contact me off list and I can describe a simple procedure. For a very quick you test can tell if your meter is too low by doing this:

1. With your DMM measure any hybrid voltage you are interested in and write the reading down.
2. Insert a 100k resistor in series with your plus probe tip and re-measure.
3. If the two readings are significantly different your meter is not adequate for the circuit you are working on.
4. In a pinch you can insert a 1 meg resistor in series and take your readings. Readings will be approx 10% low, but the meter will now not pull down the circuit as much.

Topic: 42351 Message: 42391

As far as I know, FAR does not do 2 sided boards or plated through holes. I don't recall that any of the boards in the 830 are 2 sided. Plated through holes with pads on top are almost a requirement for rugged construction and longevity. The reason the boards fail at the connector pins is because the traces underneath crack and cause opens. Plated through holes would have stopped this a long time ago.

There are much better board houses that do short runs for very reasonable costs--PCB Express is one and there are many others who can do this for a reasonable cost if the volumes are reasonable.

I truly respect your service to this country and I am grateful to you for it as I am not ashamed to be a patriot which is out of favor in the new America.

However that has nothing to do with your posting of my response to your question as an example of a "FLAME" or "RANT". Just couple of questions:

1. Did you read my response?
2. Did you comprehend my response?
3. Did you understand it was directed also to the person who was bum doping you?
4. Are you telling me you would rather be patted on the head and given bum dope than to be challenged to ask the question properly and at the same time given the correct information and the basis for the answer?

Had you couched it as "I have read my TS-530 owners manual and it says to not let plate Ip exceed 265ma yet I hear on this forum and others not to exceed either 200ma or 225ma. Which is correct Ip level and why?"

A much different question than you posed. Tells us you are a thinking person. You would have gotten your answer without being asked if you had the manual and if you had made any effort and the other person would have still been admonished to not bum dope people with parroted responses.

Gordon has asked us to drop this. I will not respond to anymore of this. If you cant understand your ownership I am wasting my time and the forums time.

From: Louis Wilen
Topic: 42351 Message: 42394

Thanks for the detailed answer, Terry.

The input impedance for my meter is > 10 MΩ < 100 pF (see http://assets.fluke.com/datasheets/2155a.pdf), so it should be fine for measuring most of the stable things that I deal with.

For capacitor testing, I have a capacitance meter and a “Blue ESR meter”. My Fluke 179 also has a capacitor test function, but my dedicated capacitance meter has a wider range that the Fluke, so it was worth the cost (to me).

But I understand your points about the advantages of using an analog meter to see nulls and peaks. Thanks for all this info.

Jerry,

The manuals on BAMA are really USER manuals. No assembly information.

I have the assembly manual but I need your email address to send it to you.

Well best test for your Fluke is to try to measure your hybrid AGC bus voltage. That will tell you all you need to know.

Yes I use my LCR bridge to measure capacitance even though my DMM has the feature as you say it is not as accurate. I also have the Antek Blue ESR meter and find it not to be very useful on hybrids due to the way the capacitors are mounted flush on the boards. In most cases not possible to get on the leads to test them in circuit. If I have to remover board to access the cap then most likely will replace it. Also takes some experience to interpret the results and even with some rules of thumb I have developed I find it is best to have a new cap to compare with. I try to look at data sheets, but cant always find them and they dont always list the ESR. I think the ESR meter would be more useful in older boat anchor gear that has point to point wiring and caps mounted on terminal strips.

Take Care
Terry

>
>
> You do not have to worry about any "reactive component" at input of your Fluke.
>
> People have already pretty much described why you want analog VTVM for tuning, peaking, nulling. If you ever want to do any FM discriminator work you would appreciate the large zero center analog meter. Cant use a DMM to check

inter-stage capacitor leakage. The DMM will miss the charge kick. Also the analog VTVM can be placed across 8 ohm dummy load at speaker and measure the audio frequency voltage (a service manual test)as they have AF ac ranges of approx 15khz to 20khz. Most DMMs fall off at 1 khz ac voltage max.
>
> Lastly, the ability to look up from the rig with your hands in it and at a glance see what you have is better than watching and waiting on your DMM. Experienced bench tech appreciates this ability. Part of the reason digital watches never really took off and replaced analog.
>
> Wait a minute I have a bar graph on mine to see nulls and peaks. Yes but still not same as analog meter movement. Analog is continuous and your bar graph is being updated at 20 to 40 times per second if you have a good DMM.
>
> In addition to being better for peaking Het Osc, carrier suppression, and neutralizing the high input impedance of the VTVM is a must for AGC and ALC bus work and Oscillator work as the others have pointed out.
>
> Problem is that not all DMMs are true 10 meg ohm and/or not on all ranges. Many cheaper DMMs are designed for home and auto use and for electricians and not for radio electronics.
>
> An electrician does not want a high Z meter. He is usually more interested in detecting the presence of voltage and proving it is not there before he installs safety grounds or bare hand touches. If he uses a high-Z DMM to check voltage in a distribution panel where feed breaker has been opened he may still read voltage. This voltage is ghost or phantom voltage due to the cables running in close proximity in the duct or raceway. The long runs results in inductive and capacitive coupling from an energized conductor to the de-energized one. He cannot ignore this voltage. To do so can result in a flash or electrocution. So he wants a DMM designed for an electrician. When it reads voltage that voltage is really there. When there is this phantom voltage present the low-Z input of the DMM will pull down this voltage and not display it and present this problem for him. Many DMMs that you see at Lowes or Home Depot are designed for electricians and not radio electronics.
>
> Fluke among others make DMMs with certain ranges that are low Z by design just for industrial electricians.
>
> Lesson is you need to read the specs on any DMM you intend to purchase. Some of the worst ones I have measured are the Harbor Freight $9.95 meters and some of the Sears meters. The Harbor Freights measure around 900k ohm input making them not useable for our Kenwood work beyond power supply measurements. As previously noted we cannot use a low Z DMM. It will pull or shut down our oscillators and will peg the S-meter and shut down the receiver AGC control bus and pull down the ALC bus to no indication.
>
> If you already have a DMM you can test it by:
> 1. RF gain full CW
> 2. Rig on dummy load
> 3. AF gain at comfortable listening level
> 4. Locate your AGC bus connection at the IF board or RF board molex connectors. Connect your DMM and try to measure this voltage (voltage should be same as you have set your RF-1 at AVR board typically around 3.3 to 3.6vdc).
> 5. Anything less than 10 meg input will drive the S-meter up scale and drive the receiver gain down. Even with a 10 meg meter you will not be able to accurately measure the AGC bus voltage. The Harbor Freight special I mentioned will peg the S-meter and shut down your receiver.
>
> Summary:
> 1. If have no meter buy a 11 meg analog VTVM and single diode and 3 diode rf probe. With this meter and probes you can make every AC, DC and RF voltage reading in the radio including all required and listed in the service manual.
>
> 2. A 10 meg FET based analog meter may be ok as long as the input Z is not range dependent. Some will be OK and

others can go as low as 2 megs on some ranges.
>
> 3. There is a place for a DMM on Hybrid bench as Mike and others note. Great for power supply measurements, transistor CBE, FET DSG, and resistance readings.
>
> 4. If you are going to buy a DMM go on line and read specs. Pay attention to the input Z on all ranges and also look at current reading burden. Not a function you will use a lot, but some have horrible burden and cannot accurately read DC ma levels. Can need this for power supply troubleshooting.
>
> 5. Buy as much speed and resolution as you can afford in your DMM. Dont confuse resolution with accuracy. I have a 40,000 count true RMS and it is sure nice to be able to hand pick resistors like a 2.7k resistor at 2699.85 ohms. A must for picking meter multipliers.
>
> Lastly, if after you do the AGC bus test with your DMM and are interested in measuring the input Z of your DMM contact me off list and I can describe a simple procedure. For a very quick you test can tell if your meter is too low by doing this:
>
> 1. With your DMM measure any hybrid voltage you are interested in and write the reading down.
> 2. Insert a 100k resistor in series with your plus probe tip and re-measure.
> 3. If the two readings are significantly different your meter is not adequate for the circuit you are working on.
> 4. In a pinch you can insert a 1 meg resistor in series and take your readings. Readings will be approx 10% low, but the meter will now not pull down the circuit as much.

I do not use a DMM for troubleshooting in my shop. I learned on a RCA senior voltohmist in high school tv shop and have one of these to this day with 3 more in the closet for backup. There is a battery in them that needs to be changed and I rotate them each year after going thru them before replace it back on the bench. These meters are large and I am so used to it I hardly ever need to "Look" at the meter, just glance and I know what it says. The DMM I use for on the road troubleshooting because the RCA is too big for the toolbox. Brad KB2CHY

Thanks for all the replies.

I never considered that a DMM might have enough reactance to affect readings. My DMM (Fluke 179) is a "true RMS" meter, so I would expect that it has some circuitry that removes the reactive component from measurements - but I'm not certain. Maybe others can comment on this.

What he said plus one other thing. A good VTVM generally will have a lesser loading effect on the circuit under test.

This is a function of input REACTANCE (not just input resistance), I am pretty sure.

If you check the same RF circuit with a VTVM and a DMM the VTVM will measure a higher voltage in every case I've done this comparison. Less load on the circuit equals greater -accuracy-.

Knowing the difference between "precision" and "accuracy" is key.

Brad: You were rich! I could never afford a Senior Voltohmyst.

A very nice meter. Same 12AU7 bridge circuit as all the others, but nicer package ,PC board instead of point to point wiring, and bigger meter. I like the low 0.50 vdc range that others dont have. Smart to have spares. Can keep going for a life time. Enjoy.

Topic: 42339 Message: 42399

Good morning Bob and Jerry,

Bama does have the 324's construction manual at the following bama.edu link

http://bama.edebris.com/download/eico/324const/EICO%20324%20CONSTRUCTION%20MANUAL.pdf

Bama also has the 324's instruction manual at the following bama.edu link

http://bama.edebris.com/download/eico/324/RF%20Gen%20Mod%20324.pdf

Jerry, if you already have the two manuals, construction and
instruction, for the 324 then disregard this.

A check of the voltages would be my first suggestion, after a thorough visual inspection and, where necessary, replacement of components such as the filter caps C3A/B. Also check all grounds, especially those that connect to the chassis through a terminal strip and/or ground lug to the chassis with machine screw, washer, and nut. Loosen the nuts and clean the area between the washer and the chassis either by moving the ground lugs side to side or by giving that area a shot of cleaner and repeat the movement. If the connection has a star washer, a simple movement (side to side) will usually regain the connection once the nut is tightened.

You might consider changing the 2 prong AC power cable and plug with a 3 prong grounded power cable. If you do that, the new 3 prong power cable's "Black" wire and fuse holder should be in series with the main power switch, S2B, Black wire to one side of the fuse holder and main power switch wafer S2B to the other side of the fuse holder. The "White" wire is connected to the power transformer's other primary winding (see the 324's schematic in the manual for details on power transformer's primary wiring and switch S2B).

Good morning,
Let's not start this crap again. Unless you find error in any of the info I would suggest printing and filing it in the notebook you should be keeping. This is a technical hobby. Some of these guys are experts and I for one appreciate their willingness to help me. Besides, none of them are as tough as my old Elmer. Now, let's put on our big boy pants and pay ATTENTION. Stop acting like children. Of course, this is just my opinion. Yall are free to do as you see fit. Enjoy the rest of the day God has given us.

I have a Heathkit IM-28 which is the wide "BENCH" VTVM with the large meter.

It sits in my closet because it is too large for my bench!

Brad: You were rich! I could never afford a Senior Voltohmyst.

A very nice meter. Same 12AU7 bridge circuit as all the others, but nicer package ,PC board instead of point to point wiring, and bigger meter. I like the low 0.50 vdc range that others dont have. Smart to have spares. Can keep going for a life time. Enjoy.

Good morning Bob and Jerry,

Bama does have the 324's construction manual at the following bama.edu link

http://bama.edebris.com/download/eico/324const/EICO%20324%20CONSTRUCTION%20MANUAL.pdf

Bama also has the 324's instruction manual at the following bama.edu link

http://bama.edebris.com/download/eico/324/RF%20Gen%20Mod%20324.pdf

Jerry, if you already have the two manuals, construction and
instruction, for the 324 then disregard this.

A check of the voltages would be my first suggestion, after a thorough
visual inspection and, where necessary, replacement of components such
as the filter caps C3A/B. Also check all grounds, especially those that
connect to the chassis through a terminal strip and/or ground lug to the
chassis with machine screw, washer, and nut. Loosen the nuts and clean
the area between the washer and the chassis either by moving the ground
lugs side to side or by giving that area a shot of cleaner and repeat
the movement. If the connection has a star washer, a simple movement
(side to side) will usually regain the connection once the nut is tightened.

You might consider changing the 2 prong AC power cable and plug with a 3
prong grounded power cable. If you do that, the new 3 prong power
cable's "Black" wire and fuse holder should be in series with the main
power switch, S2B, Black wire to one side of the fuse holder and main
power switch wafer S2B to the other side of the fuse holder. The "White"
wire is connected to the power transformer's other primary winding (see
the 324's schematic in the manual for details on power transformer's
primary wiring and switch S2B).

Good morning Bob and Jerry,

Bama does have the 324's construction manual at the following bama.edu link

http://bama.edebris.com/download/eico/324const/EICO%20324%20CONSTRUCTION%20MANUAL.pdf

Bama also has the 324's instruction manual at the following bama.edu link

http://bama.edebris.com/download/eico/324/RF%20Gen%20Mod%20324.pdf

Jerry, if you already have the two manuals, construction and
instruction, for the 324 then disregard this.

A check of the voltages would be my first suggestion, after a thorough visual inspection and, where necessary, replacement of components such as the filter caps C3A/B. Also check all grounds, especially those that connect to the chassis through a terminal strip and/or ground lug to the chassis with machine screw, washer, and nut. Loosen the nuts and clean the area between the washer and the chassis either by moving the ground lugs side to side or by giving that area a shot of cleaner and repeat the movement. If the connection has a star washer, a simple movement

(side to side) will usually regain the connection once the nut is tightened.

You might consider changing the 2 prong AC power cable and plug with a 3 prong grounded power cable. If you do that, the new 3 prong power cable's "Black" wire and fuse holder should be in series with the main power switch, S2B, Black wire to one side of the fuse holder and main power switch wafer S2B to the other side of the fuse holder. The "White" wire is connected to the power transformer's other primary winding (see the 324's schematic in the manual for details on power transformer's primary wiring and switch S2B).

> unplugged is good.

Just use more cleaning spray. Some light work with a medium-stiff brush
to remove any caked-on dirt/dust. CAREFULLY. De-Oxit 5 (if I remember
a-right) has a lubricant in it, so just use that. I DON'T RECOMMEND
petroleum jelly, it tends to get into places it oughtn't.

Any of the control-linkage sprays or lubes for electronics will loosen
the knobs, if the shafts aren't kinked or bent. No WD-40, either, by
the way. Just haven't had any good luck with that stuff for anything
electronic. Works fine of cabinet hinges, though...

If you can, search the internet (GOOGLE.COM or I use IXQUICK.COM) for

eico model 324 signal generator schematic manual

You should be able to turn up a PDF file manual somewhere. (I'm being
lazy, didn't search it myself.) You can copy and paste that line above
to the search engine page.

See what comes up, but DO NOT pay money for it on-line. Check here
FIRST, most of those "We'll sell you a manual," places add "SUCKER!"
when you hang up the phone.

This is BASIC cleaning of equipment. It more or less applies to
ANYTHING, old, new, or in-between:

Check the circuit boards for obvious damage. Burned spots on the
phenolic side, blackened components, burned or missing traces on the

copper side, if there are circuit boards and it's not all point-to-point. (I don't remember if I've ever been under the hood of a 324, so I don't have any idea of the construction methods.) Cracked or lifted traces on circuit boards. Cold solder joints. Cracking insulation on point-to-point wiring. Loose or corroded connectors.

Also look for popped or bulging capacitors, leaking electrolytic compound, any sort of crystallized powdery residue particularly on or underneath capacitors, and particularly electrolytic capacitors.

Excess flux on solder joints, that will leave a whitish or resiny coating on things. Clean it off with flux remover (best) or isopropyl (rubbing) alcohol (cheapest) and dry THOROUGHLY.

Check coils for mashed, displaced, or broken windings. You have to lift one end of a coil (and a resistor, and a diode, and about anything else, if it's a 2-lead device) and check it for simple continuity. Won't tell you if it's still the right electrical size, but will tell you if the windings are broken.

Anyone else here still use a grid dipper?? Or am I REALLY a dinosaur??

If you take ANYTHING apart (even the CASE if it's a tricky disassembly) TAKE NOTES, or a digital snapshot of the thing as it comes apart (BOTH NOTES AND PIX), so you know how it goes back together.

Keep the screws in something that you're not going to tip over every time you reach for a tool and spread ballistically all over the room.

If possible, and if they won't be in the way of getting the next bit out, PUT THE SCREWS BACK IN THE HOLES THEY CAME OUT OF after the sub-assembly or component has been taken off the chassis or whatever. That way, you know for sure where the screw came from.

Replace and repair as you find problems. Once the obvious stuff is taken care of, then you dive into the schematic and start tracing signals and verifying biases, and making sure that power supplies are supplying power, and that kind of stuff.

The Mark I Eyeball is your best diagnostic tool when you begin with an old piece of gear.

Good Luck.

Well I acquired them through different means. Mainly it was at my job, there are 54 Central Offices and about 10 within the city lines at the local phone company. After we changed to the computer type switch we were all issued DVM Flukes to do voltage checks on the office batteries and rectifiers and such. We also had straight Triplett and Weston voltmeters with the mirror back. These were what was used by the older guys. Batteries had to be read weekly (pilot cell) and full battery reads monthly and cleaned and checked every 180 days. Most RCA meters were NEVER used and were like brand new except the battery was bad or leaky and the power cords dry and frayed. When we cleaned out old gear, I was allowed to take what I wanted of the collection. Some was for nostalgia purposes; others were for the RCA units. I grabbed 3 of them. The rest went to others and some were donated to my local high school. I am in the process now of getting one ready to replace the one on the bench. Have a good day. Brad KB2CHY

Brad: You were rich! I could never afford a Senior Voltohmyst.

A very nice meter. Same 12AU7 bridge circuit as all the others, but nicer package ,PC board instead of point to point wiring, and bigger meter. I like the low 0.50 vdc range that others dont have. Smart to have spares. Can keep going for a life time. Enjoy.

If you have a hot chassis disconnect the capacitors (C1 & C2) that are across the power line. I would expect them to be on a terminal strip where the power line cones into the unit.

They probably need replacing anyway. There are special capacitors for this application.

good morning all/ thas quite all right i have now both manuals.and much appreciation for all the help . i am going to recap the filterers change the rf out to bnc and change the power cord/ u didnt mention the green or ground wire/ or wud the hot chassis be from a missing ground connection/ also insted of 110 volts dc there is 154-160 volts on the plates/ but it now functions with rf out from cleaning the band switch i never did like working on hot chassis/ and really not sure if the freq is any where near right will double check the grounds today or clean them as suggested!

Good morning Bob and Jerry,

Bama does have the 324's construction manual at the following bama.edu link

http://bama.edebris.com/download/eico/324const/EICO%20324%20CONSTRUCTION%20MANUAL.pdf

Bama also has the 324's instruction manual at the following bama.edu link

http://bama.edebris.com/download/eico/324/RF%20Gen%20Mod%20324.pdf

Jerry, if you already have the two manuals, construction and
instruction, for the 324 then disregard this.

A check of the voltages would be my first suggestion, after a thorough visual inspection and, where necessary, replacement of components such as the filter caps C3A/B. Also check all grounds, especially those that connect to the chassis through a terminal strip and/or ground lug to the chassis with machine screw, washer, and nut. Loosen the nuts and clean the area between the washer and the chassis either by moving the ground lugs side to side or by giving that area a shot of cleaner and repeat the movement. If the connection has a star washer, a simple movement (side to side) will usually regain the connection once the nut is tightened.

You might consider changing the 2 prong AC power cable and plug with a 3 prong grounded power cable. If you do that, the new 3 prong power cable's "Black" wire and fuse holder should be in series with the main power switch, S2B, Black wire to one side of the fuse holder and main power switch wafer S2B to the other side of the fuse holder. The "White" wire is connected to the power transformer's other primary winding (see the 324's schematic in the manual for details on power transformer's primary wiring and switch S2B).

Yes mirrored scale meters were nice to avoid parallax errors. Weston commonly had them. I have a really nice Simpson 2795 FET meter that has very low UA voltage and current ranges and a nice mirrored scale meter movement.

Station batteries bring back memories. There are numerous batteries used in Fossil and Nuke plants where I spent my working life. Most were 125 vdc and 250 vdc. All feed emergency pumps, valves, control circuits. If maintained can last many years. I have taken many pilot cell readings and float readings and equalizing readings. In Nuke power draw down testing is required by terms of your license and that is a big deal test with huge banks of resistor grids and sophisticated controllers. I got involved with developing single cell charging, but NRC didnt like it. Not sure if done anymore. Had to be very careful when you told the new electrician that you would be jumpering a cell out. What a bomb!

Most of our techs came off nuke subs and those boys understand batteries and know how to equalize a battery.

In very old days power plants use to have our own frame room with rotary Stepper relays. I once went to a class in Texas and the instructor was describing an adjustment to these relays and 2 good old boys next to me looked at each other and started laughing. Instructor asked them to share with class and they said now we can go home and take those rubber bands off!

I dont keep battery in any of my VTVMs anymore. I use DMM for resistance measurements. Dont have to worry about acid wrecking them.

Enjoy those RCAs

A GDO is not an instrument that many hams find useful these days. Almost indispensable in the old days for home brewing.

Today for Kenwood service not much demand so would not rush out to buy one.

Very good for checking the main plate choke. Most hams would just do a visual. Problem is that they do not know what the design parallel resonance is and where the series resonance holes should be. I have posted all the specs here several times. When I rewind a plate choke I do Dip it, but in practice as long as you use same gauge wire and get back on same number of design turns the series resonant holes should not have shifted. (One pretty close to 24mhz and next strong one at 33 mhz which is no concern).

Before digital LCR bridge became common and affordable for the bench would use GDO along with a standard capacitor and standard inductor to calculate unknown inductors and capacitors by placing then in parallel resonant config and finding the Dip and then plug that value into the Resonant Frequency formula and solving to find your unknown capacitor or inductor. Worked pretty well if you were winding your own choke coils or making your own capacitors

Also very good for dipping any antenna trap you have or want to make and for testing crystals.

Thats about the common uses I can think of.

There are some books on line you can read on how to use and several good old QST articles in ARRL archives. Important thing is use low level of grid current (maybe half scale) and very loose coupling and need a freq counter with sniffer loop near the GDO coil to read the frequency of the DIP. The dials are not very accurate.

I have the classic Millen 90651 and the Measurements 59. The Measurements is a better dipper, but harder to find a good one and the Millen is a fine GDO. Kenwood makes a nice looking unit that I suspect has FET oscillator. I have no experience with it. Stay away from the Heath Tunnel Dipper. It does not have enough "horsepower". As you say the MFJ-259 has GDO coils but again I have no experience with it in that mode.

Very good for checking the main plate choke. Most hams would just do a visual. Problem is that they do not know what the design parallel resonance is and where the series resonance holes should be. I have posted all the specs here several times. When I rewind a plate choke I do Dip it, but in practice as long as you use same gauge wire and get back on same number of design turns the series resonant holes should not have shifted. (One pretty close to 24mhz and next strong one at 33 mhz which is no concern).

Before digital LCR bridge became common and affordable for the bench would use GDO along with a standard capacitor and standard inductor to calculate unknown inductors and capacitors by placing then in parallel resonant config and finding the Dip and then plug that value into the Resonant Frequency formula and solving to find your unknown capacitor or inductor. Worked pretty well if you were winding your own choke coils or making your own capacitors

Also very good for dipping any antenna trap you have or want to make and for testing crystals.

Thats about the common uses I can think of.

There are some books on line you can read on how to use and several good old QST articles in ARRL archives. Important thing is use low level of grid current (maybe half scale) and very loose coupling and need a freq counter with sniffer loop near the GDO coil to read the frequency of the DIP. The dials are not very accurate.

I have the classic Millen 90651 and the Measurements 59. The Measurements is a better dipper, but harder to find a good one and the Millen is a fine GDO. Kenwood makes a nice looking unit that I suspect has FET oscillator. I have no experience with it. Stay away from the Heath Tunnel Dipper. It does not have enough "horsepower". As you say the MFJ-259

has GDO coils but again I have no experience with it in that mode.

If you have a hot chassis disconnect the capacitors (C1 & C2) that are across the power line. I would expect them to be on a terminal strip where the power line cones into the unit.

They probably need replacing anyway. There are special capacitors for this application.

Good morning Bob and Jerry,

Bama does have the 324's construction manual at the following bama.edu link

http://bama.edebris.com/download/eico/324const/EICO%20324%20CONSTRUCTION%20MANUAL.pdf

Bama also has the 324's instruction manual at the following bama.edu link

http://bama.edebris.com/download/eico/324/RF%20Gen%20Mod%20324.pdf

Jerry, if you already have the two manuals, construction and
instruction, for the 324 then disregard this.

A check of the voltages would be my first suggestion, after a thorough
visual inspection and, where necessary, replacement of components such
as the filter caps C3A/B. Also check all grounds, especially those that
connect to the chassis through a terminal strip and/or ground lug to the
chassis with machine screw, washer, and nut. Loosen the nuts and clean
the area between the washer and the chassis either by moving the ground
lugs side to side or by giving that area a shot of cleaner and repeat
the movement. If the connection has a star washer, a simple movement
(side to side) will usually regain the connection once the nut is tightened.

You might consider changing the 2 prong AC power cable and plug with a 3
prong grounded power cable. If you do that, the new 3 prong power
cable's "Black" wire and fuse holder should be in series with the main
power switch, S2B, Black wire to one side of the fuse holder and main
power switch wafer S2B to the other side of the fuse holder. The "White"
wire is connected to the power transformer's other primary winding (see
the 324's schematic in the manual for details on power transformer's
primary wiring and switch S2B).

42412. Digital Interface for Kenwood

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-30 20:13:41 UTC
From: sceneryguru
Topic: 42412 Message: 42412

Good Afternoon Group:

Some of you may recall that I recently liquidated my entire TS-820S station. In doing a bit of house keeping I discovered my Digital Interface for Kenwood Transceivers. Details are as follows:

Our interface includes a 3 ft cable which will allow you to have your radio and computer up to 5.5 ft apart, which is probably far enough for most people. Donner's Digital Interface will interface the Kenwood Amateur (Ham) radios listed below that use a 4 pin microphone connector, to computers for working digital modes like PSK31, RTTY, SSTV, AMTOR, CW, and many others.

You won't have to set any jumpers or change anything on the interface. Just plug it into your radio and computer, download and setup your software and you are ready to get on the air.

This is a brand NEW interface, never used, only taken out of its packaging for inspection.

Kenwood Transceivers:

TS-120, TS-130, TS-180
TS-311, TS-510, TS-511
TS-520, TS-530,TS-600
TS-700, TS-770, TS-801
TS-820/S, TS-830, TS-900
TX-310, TR-1300, TR-2200
TR-2300, TR-5200, TR-7010
TR-7200, TR-7400, TR-7500
TR-8000, TR-8200, TR-8300

I'll take 35.00 shipped FREE via USPS Priority mail. I would prefer payment through PayPal. Any questions, please don't hesitate to contact me off list. - K3SSB at verizon.net

Thanks to the group for indulging me. - tnx es 73

Search for "film capacitor" then refine it to the size
(microfarads/picofarads and working voltage) you need

Changing to a 3 prong grounded power cable, look at the schematic, you will notice there are 2 wires from the AC plug. One goes to AC switch S2B switch and the other goes to the other power transformer primary winding.

The new 3 prong power cable has 3 wire, BLACK (AC HOT), WHITE (AC NEUTRAL) and GREEN (SAFETY GROUND).

The "BLACK" (AC HOT) wire connects to one side of a fuse holder. The other side of the fuse holder connects to AC switch S2B.

The "WHITE" (AC NEUTRAL) wire connects to the other power transformer lead.

The "GREEN" (SAFETY GROUND) wire connects to the chassis.

More than likely, as one response said, these connections are made at a terminal strip.

The Eico 324 generator's power rating is 15 watts at 117VAC (see the instruction manual, page 3, next to POWER REQUIREMENTS). Therefore, the fuse is 1/2 amp slow blow (15 / 117 = .128amps). If you don't have a 1/2 amp then a 3/4 amp fuse will also be okay. I wouldn't use a fuse higher than 3/4 amp.

C1 and C2 across the power transformer's primary windings are RF and noise bypass capacitors. It not uncommon for these capacitors, over time, to become leaky causing a tingle when touching the chassis. I have a Heathkit DX-40 transmitter that had those caps and I removed them. If you replace them, they are .01ufd at 400 volts according to the part lists but if you can't find them at 400 volts then 1500 volt caps will work. The higher voltage rating won't change the circuit just be capable of handing up to 1500 volts. I changed the 2 prong power cable in my DX-40 to a 3 prong power cable and inserted a fuse in series with the BLACK (AC HOT) lead plus removed the AC bypass caps and no longer have the tingle.

It's a good idea to change the screw on output connectors to BNC Female sockets. I did that with my Heathkit IG-102, both AF and RF sockets. You should also obtain a BNC "T" connector so you can connect a frequency counter and a probe to the circuit under test at the same time. The frequency counter will act as a "Digital Display" so you can adjust the generator to the desired frequency you want without "guessing" with the analog dial. More often than not those analog dials are no where near accurate so a frequency counter will eliminate the guessing.

Also, the generator has an built in audio generator. The audio generator can be used to apply an audio signal to an audio amp under test or it

can be used to modulate the generator's RF signal. This is okay for simple receiver detector testing in a receiver.

Here is a simple trick where a signal generator can help in troubleshooting. If you suspect an oscillator has failed, you can use a signal generator to "substitute" for the suspected failed oscillator. Inject the normal oscillator frequency into the mixer and if the receiver comes to life then you know where the problem is, the oscillator has failed. I used my IG-102 when troubleshooting a TS-120. I substituted the signal generator for the CAR Unit's 8Mhz oscillator and the TS-120 came to life which verified my suspicions the 8Mhz oscillator had failed. I had a similar problem in a Collins 75A2 receiver when the PTO failed. I injected a frequency within the range of the PTO to the PTO mixer and the receiver came to life. If you do this, make sure there is no DC voltage on the connection. Verify this using a DC volt meter. You can also keep a .01ufd 600VDC cap in series with the generator's probe to block any DC voltage less than 600VDC from being fed to the generator's output. This is where some jumpers come in handy, alligator clips on both ends of the jumper. Make all connections to the circuit with power OFF, check for shorts in the connections and only apply power when it's safe, no short and no DC voltage applied to the generator's output through the probe.

The Eico signal generator is a simple basic RF and AF signal generator, it's not top quality so don't expect it to be. It's okay for performing MF and HF alignments but I wouldn't use it to make critical adjustments.

Jerry wrote"
"still not sure about grounding the chassis tho"

Disconnect C1 and C2 and measure the resistance between the transformer primary and the chassis .

There should be none. If there is any resistance between the transformer primary and the chassis with C1 and C2 disconnected you do have a problem.

Search for "film capacitor" then refine it to the size
(microfarads/picofarads and working voltage) you need

The right part arrived, in a really short time, at a reasonable price. Can't ask for better. But got them. Thanks for the extras, too. "Case screws" come in handy all the time.

Several folks have commented about your line filter caps. They are there to shunt rf on the 120VAC line to chassis ground. Sources of RF include portable appliances like mixers and blenders that have brushes and commutators that will arc and place a signal on the 60hz which would then be coupled into your Sig Gen. Three common ways to suppress this in old days. 1.Choke coils in series in the hot and grd leads to transformer primary. 2 A shunt capacitor across the hot and grd leads. and most commonly 3. Capacitors from each line to chassis ground on primary side of your transformer.

Your EICO has No. 3 configuration. If either of these two caps become leaky the chassis can come hot and be a shock hazard. These capacitors see the most severe duty in our radios and test gear because as long the line cord is plugged in to 120vac receptacle the capacitors are energized at all times. This is why new code requires safety capacitor to reduce shock and fire hazard from continuous duty cycle.

So today as Bob has stated you need to replace them with Safety Capacitors. Type X go across the line and Type Y from line to chassis. Easier to just use a universal safety capacitor designated as a type X1/Y2. Can buy these for 10 for $1.00 on Ebay. Check there before buying from Mouser unless you are making an order to Mouser. Capacitance value is not critical. Try to buy as close to values of the current caps. You can remove them and run without them and Sig gen will work just fine, but I would replace them with new Safety Caps.

As for replacing your wax tubular capacitors someone already mentioned using Film capacitors. That is correct but there are large variety of Film caps. Pretty much any of these will work. Plastic/polyester. Metalized polyester. Metalized polypropylene. Polystyrene and Mylar. Polypropylene and polystyrene are better for high frequency applications so I tend to buy and use them. The old wax paper are usually tubular in shape and may even have some "black beauties". Any rectangular brownish ones are likely Mica.

You should easily find Film capacitors at Mouser to replace any paper caps in your 324. Does not have to be Mylar. Mylar is just Dupont trade name.

> Very good for checking the main plate choke. Most hams would just do a visual. Problem is that they do not know what the design parallel resonance is and where the series resonance holes should be. I have posted all the specs here several times. When I rewind a plate choke I do Dip it, but in practice as long as you use same gauge wire and get back on same number of design turns the series resonant holes should not have shifted. (One pretty close to 24mhz and next strong one at 33 mhz which is no concern).
>
> Before digital LCR bridge became common and affordable for the bench would use GDO along with a standard capacitor and standard inductor to calculate unknown inductors and capacitors by placing then in parallel resonant config and finding the Dip and then plug that value into the Resonant Frequency formula and solving to find your unknown capacitor or inductor. Worked pretty well if you were winding your own choke coils or making your own capacitors

>
> Thats about the common uses I can think of.
>
> There are some books on line you can read on how to use and several good old QST articles in ARRL archives. Important thing is use low level of grid current (maybe half scale) and very loose coupling and need a freq counter with sniffer loop near the GDO coil to read the frequency of the DIP. The dials are not very accurate.
>
> I have the classic Millen 90651 and the Measurements 59. The Measurements is a better dipper, but harder to find a good one and the Millen is a fine GDO. Kenwood makes a nice looking unit that I suspect has FET oscillator. I have no experience with it. Stay away from the Heath Tunnel Dipper. It does not have enough "horsepower". As you say the MFJ-259 has GDO coils but again I have no experience with it in that mode.

I forgot to ask did someone respond to your high anode voltage on 12AU7? If not it may be possible that someone has already replaced the selenium rectifier with a silicon diode as I suggested you do in earlier post, but they may not have added the necessary series dropping resistor. Must do that.

If you just replace the selenium you can end up with DC supply voltage 15 to 20 vdc higher. For example: 120 vac secondary will charge filter caps to the peak or 120 X 1.414 = 170 vdc. Output voltage at tubes plate will be somewhat less than this due to drop across the Pi filter (C-R-C).

So do you know what a selenium rectifier looks like? If not, it is a square cube that has stack of thin metal plates. Secondary lead of power transformer will run to terminal on it. If it has been replaced they should have added the series resistor from approx 100 to 200 ohms at 2-5 watts. Often have to play with the value to tweak it in.

If selenium is there strongly recommend you replace it with 1N4007 silicon rectifier diode (mouser or radio shack). If you do not you will not like the odor when it does fail. It is not a joke and can be a fire and the fumes are toxic.

I usually mount the silicon diode and series resistor on a phenolic terminal strip. Just dont connect to the ground lug!

Hello again Terry,

I think my problem might be a loose/cracked connection somewhere, and those are hard to track down. I'm saying this because as I was following your instructions and looking into other measurements following some schematics I have, I flipped the rig and it started working. I then flipped it again and it stopped working, and then tried to flip it one more time and did not work anymore. So I proceeded to make measurements on the transistors on the AF-AVR board, and then, I screwed in place the AF-AVR board again, and now the radio is working again (even after I put it right-side up again). So I'm guessing it's not a component failure but more of a connection failure, right?

In any case, here are the measurements I took when the rig was not working properly, and then after it started working properly:

On the IF board, Conn IF-3, using a 10Meg DMM, I got the following values:

1. With power off measure AGC bus resistance at Pin 11. Should be approx 1.7 meg ohm.
>>> I actually got 2.7 meg ohms between pins 11 and 17 (without removing any of the connectors).

2. With power on measure RF-1 at Pin 8. Should be approx 3.4vdc
>>> I measured 1.96V when not working, 2.9V when working.

3. With power on and RF gain pot full CW measure AGC at Pin 11. Should be approx 2.8vdc with a 11 meg VTVM and somewhat less with a 10 meg ohm DMM.
>>> When not working I measured 1.47V, and the schematics I have said it should be at 3V (same as you said). I also measured AGC at pin 7 on RF board (RF-1 Conn), and also got 1.47V. When working I measured 2.2V.

4. If RF-1 is OK and AGC is very low you can try applying 3vdc to Pin 11 and see if rig comes alive. If you do not have a bench supply then use a Radio Shack battery holder and series up couple of 1.5vdc C or D cells. Connect negative lead to chassis ground and touch positive 3vdc lead to Pin 11. Rig should come alive. Watch S meter and see if it comes off the peg.
>>> I did not attempt this as you mentioned to do this "if" RF-1 was OK, which in this case it does not look like it's OK.

5. I forgot also measure voltage at Pin 6 AGL should be same as what you read at Pin 11 AGC. AGL and AGC at IF board should be same point electrically as they are connected in receive mode thru the NC contact of the aux relay you just cleaned. But possible to have bad molex connections at Relay board and/or IF board.
>>> When not working I measured 1.47V, so it does look like AGL and AGC are connected. When working I measured 2.2V.

6. Also apply temporary 3vdc to Pin 6 and see if S meter comes off the peg.
>>> I again, I did not attempt this for the same reason as mentioned in item 4.

Like I said at the beginning, and following some troubleshooting suggestions from the Service Manual, I checked the Q1 and Q2 transistors on the AF-AVR board and their voltages on B/C/E were correct, and then, for Q3, I only checked pins 1, 3, 5 and 6, and they all gave me values as shown in the schematics. Those schematics are very handy!!! :-)

So, next time it fails, should I look into the RF board since the IF board did not have correct AGC or RF-1 voltages? Or do you suggest some other places I should make measurements to see if I can spot where the intermittent connection is?

Thanks again for your help Terry! I have a feeling I'm going to really get to know and love my new rig. ;-)

OK Cesar:

With rig not working I think you measured RF-1 at approx 1.9vdc. At that level you will have very low or no Receive because the AGC bus control voltage to the gain controlled devices (IF and RF amp mosfets) is too low.

I think you said when rig is working you measured approx 2.9vdc at RF-1. You can adjust that with trim pot VR-1 on the AVR board. You want nothing less than 3.3vdc. Receiver will work on 2.9vdc, but not optimum.

It sounds like you have a high resistance ground on the AVR board ground plane. This can account for the low RF-1 voltage. I would loosen all the hold down screws and re-tighten (snug) them. No need to install star lock washers. Just dont strip the screws out.

Your resistance on the AGC bus of approx 2.7 meg is good. Tells you no shorts on it (like failed meter FET) and no leaky timing caps to pull it down.

It is ok to try the temporary 3vdc on the AGC bus when it is at 1.9 or 2.9 vdc. You are simply paralleling dc power supplies like jumpering your car battery with another. It will not hurt anything. No reason to do it if you have consistent 3.3 vdc. I only suggest it when you have low AGC voltage on the bus.

Again: First suggest you loosen and tighten AVR board mounting screws and then adjust RF-1 voltage to 3.3vdc and see of receive now acts normal. As I recall there are couple of different AVR board revisions and the ground plane is not continuous around board perimeter so important that all hold down screws make good contact with chassis.

Thanks again Terry!

I have a question and a comment based on your last feedback.

1) When you say that I can adjust RF-1 to be 3.3V, you are assuming I'm not using a DMM, right? I think you said with a DMM I would be seeing smaller values.

2) I took the AVR board out to make the measurements on the Q1-3 on the back side, and when I put it back in its place I made sure the screws were nice and tight, maybe that's why it's working now. I did notice one of the 4 screws was missing, so I'll make sure I find a forth one and put it in place.

Thanks again!

>
> I think you said when rig is working you measured approx 2.9vdc at RF-1. You can adjust that with trim pot VR-1 on the AVR board. You want nothing less than 3.3vdc. Receiver will work on 2.9vdc, but not optimum.
>
> It sounds like you have a high resistance ground on the AVR board ground plane. This can account for the low RF-1 voltage. I would loosen all the hold down screws and re-tighten (snug) them. No need to install star lock washers. Just dont strip the screws out.
>
> Your resistance on the AGC bus of approx 2.7 meg is good. Tells you no shorts on it (like failed meter FET) and no leaky timing caps to pull it down.
>
> It is ok to try the temporary 3vdc on the AGC bus when it is at 1.9 or 2.9 vdc. You are simply paralleling dc power supplies like jumpering your car battery with another. It will not hurt anything. No reason to do it if you have consistent 3.3 vdc. I only suggest it when you have low AGC voltage on the bus.
>
> Again: First suggest you loosen and tighten AVR board mounting screws and then adjust RF-1 voltage to 3.3vdc and see of receive now acts normal. As I recall there are couple of different AVR board revisions and the ground plane is not continuous around board perimeter so important that all hold down screws make good contact with chassis.

I'm saying this because as I was following your instructions and looking into other measurements following some schematics I have, I flipped the rig and it started working. I then flipped it again and it stopped working, and then tried to flip it one more time and did not work anymore. So I proceeded to make measurements on the transistors on the AF-AVR board, and then, I screwed in place the AF-AVR board again, and now the radio is working again (even after I put it right-side up again). So I'm guessing it's not a component failure but more of a connection failure, right?

Good Afternoon Group:

Some of you may recall that I recently liquidated my entire TS-820S station. In doing a bit of house keeping I discovered my Digital Interface for Kenwood Transceivers. Details are as follows:

Our interface includes a 3 ft cable which will allow you to have your radio and computer up to 5.5 ft apart, which is probably far enough for most people. Donner's Digital Interface will interface the Kenwood Amateur (Ham) radios listed below that use a 4 pin microphone connector, to computers for working digital modes like PSK31, RTTY, SSTV, AMTOR, CW, and many others.

You won't have to set any jumpers or change anything on the interface. Just plug it into your radio and computer, download and setup your software and you are ready to get on the air.

This is a brand NEW interface, never used, only taken out of its packaging for inspection.

Kenwood Transceivers:

TS-120, TS-130, TS-180
TS-311, TS-510, TS-511
TS-520, TS-530,TS-600
TS-700, TS-770, TS-801
TS-820/S, TS-830, TS-900
TX-310, TR-1300, TR-2200
TR-2300, TR-5200, TR-7010
TR-7200, TR-7400, TR-7500
TR-8000, TR-8200, TR-8300

I'll take 35.00 shipped FREE via USPS Priority mail. I would prefer payment through PayPal. Any questions, please don't hesitate to contact me off list. - K3SSB at verizon.net

Thanks to the group for indulging me. - tnx es 73

Subject: [TS-520_820_530_830] Re: eico324!!

Several folks have commented about your line filter caps. They are there to shunt rf on the 120VAC line to chassis ground. Sources of RF include portable appliances like mixers and blenders that have brushes and commutators that will arc and place a signal on the 60hz which would then be coupled into your Sig Gen. Three common ways to suppress this in old days. 1.Choke coils in series in the hot and grd leads to transformer primary. 2 A shunt capacitor across the hot and grd leads. and most commonly 3. Capacitors from each line to chassis ground on primary side of your transformer.

Your EICO has No. 3 configuration. If either of these two caps become leaky the chassis can come hot and be a shock hazard. These capacitors see the most severe duty in our radios and test gear because as long the line cord is plugged in to 120vac receptacle the capacitors are energized at all times. This is why new code requires safety capacitor to reduce shock and fire hazard from continuous duty cycle.

So today as Bob has stated you need to replace them with Safety Capacitors. Type X go across the line and Type Y from line to chassis. Easier to just use a universal safety capacitor designated as a type X1/Y2. Can buy these for 10 for $1.00 on Ebay. Check there before buying from Mouser unless you are making an order to Mouser. Capacitance value is not critical. Try to buy as close to values of the current caps. You can remove them and run without them and Sig gen will work just fine, but I would replace them with new Safety Caps.

As for replacing your wax tubular capacitors someone already mentioned using Film capacitors. That is correct but there are large variety of Film caps. Pretty much any of these will work. Plastic/polyester. Metalized polyester. Metalized polypropylene. Polystyrene and Mylar. Polypropylene and polystyrene are better for high frequency applications so I tend to buy and use them. The old wax paper are usually tubular in shape and may even have some "black beauties". Any rectangular brownish ones are likely Mica.

You should easily find Film capacitors at Mouser to replace any paper caps in your 324. Does not have to be Mylar. Mylar is just Dupont trade name.

>
> Today for Kenwood service not much demand so would not rush out to buy one.
>
> Very good for checking the main plate choke. Most hams would just do a visual. Problem is that they do not know what the design parallel resonance is and where the series resonance holes should be. I have posted all the specs here several times. When I rewind a plate choke I do Dip it, but in practice as long as you use same gauge wire and get back on same number of design turns the series resonant holes should not have shifted. (One pretty close to 24mhz and next strong one at 33 mhz which is no concern).
>
> Before digital LCR bridge became common and affordable for the bench would use GDO along with a standard capacitor and standard inductor to calculate unknown inductors and capacitors by placing then in parallel resonant config and finding the Dip and then plug that value into the Resonant Frequency formula and solving to find your unknown capacitor or inductor. Worked pretty well if you were winding your own choke coils or making your own capacitors
>
> Also very good for dipping any antenna trap you have or want to make and for testing crystals.
>
> Thats about the common uses I can think of.
>
> There are some books on line you can read on how to use and several good old QST articles in ARRL archives. Important thing is use low level of grid current (maybe half scale) and very loose coupling and need a freq counter with sniffer loop near the GDO coil to read the frequency of the DIP. The dials are not very accurate.
>
> I have the classic Millen 90651 and the Measurements 59. The Measurements is a better dipper, but harder to find a good one and the Millen is a fine GDO. Kenwood makes a nice looking unit that I suspect has FET oscillator. I have no experience with it. Stay away from the Heath Tunnel Dipper. It does not have enough "horsepower". As you say the MFJ-259

has GDO coils but again I have no experience with it in that mode.

weeeellll hmmmm, it is a rectangular black thing abt 1/2 x3/4,x3/4/ the tag on it has a sorta s on theAnode?and sorta regular straight line on the bottom of the arrow hihi/ so dont know if that s indicates selenium or not/ ive seen selenium diodes in battery chargers but bigger then this by far and never encased in epoxy or whatever
but that wud explain the hi voltage on plates for sure cause i dont see any resistors other then the schematics ones/ i might even have some 1n4007 laying on the bench awaiting to be used may even have the resistor salvaged from some tv or somethin/ agin thanks Terry / U can be my Mentor anytime/ it is really nice to have someone thats willing to spend time helping /maybe someday i can pass it forward thanks

Subject: [TS-520_820_530_830] Re: eico324!!

I forgot to ask did someone respond to your high anode voltage on 12AU7? If not it may be possible that someone has already replaced the selenium rectifier with a silicon diode as I suggested you do in earlier post, but they may not have added the necessary series dropping resistor. Must do that.

If you just replace the selenium you can end up with DC supply voltage 15 to 20 vdc higher. For example: 120 vac secondary will charge filter caps to the peak or 120 X 1.414 = 170 vdc. Output voltage at tubes plate will be somewhat less than this due to drop across the Pi filter (C-R-C).

So do you know what a selenium rectifier looks like? If not, it is a square cube that has stack of thin metal plates. Secondary lead of power transformer will run to terminal on it. If it has been replaced they should have added the series resistor from approx 100 to 200 ohms at 2-5 watts. Often have to play with the value to tweak it in.

If selenium is there strongly recommend you replace it with 1N4007 silicon rectifier diode (mouser or radio shack). If you do not you will not like the odor when it does fail. It is not a joke and can be a fire and the fumes are toxic.

I usually mount the silicon diode and series resistor on a phenolic terminal strip. Just dont connect to the ground lug!

Hello all, new to the group!
I've been running kenwood rigs since I first got my novice ticket (now General class) 20+ year ago.

Last week I picked up a nice looking Kenwood 520. I was told by the PO it had died during a QSO on 20 meters, It quit both TX and receive.
Got it home and it is dead on all bands in receive. However when you'd push in the WWV button it will receive across that band just fine.
Also noticed at times when you'd push the button in the JJY position it would receive fine for about 2-5 seconds then die, just static.
Also from a cold start it would receive fine (sometimes) for about the same time. Now I cannot get it to receive at all in the JJY position! WWV still works fine. It has a jumper (solder blob) across the 8 and 9 pins on the vfo plug.

TX is a different story, I'm getting about 70 watts on 80M, 25 on 40M, 10-18 watts or so on 20-10M. Not real worried about the TX side yet, need to get the receive going.

I have cleaned the relays, Checked the WWV/JJY switch, not broken and has continuity in both positions. Loosened and retightened all screws, checked for dead end wires, Checked the voltages on the AVR board for 9 volts and 3.3 volts there ok. Not even sure where to really start looking? Just done a few basic's.

Now I am new to troubleshooting and repair, only armed with a Volt/Ohm meter, A Blown up schematic of the 520, Both the manual and service manual. Would really like to get this old gal working again!
Any help, guidance would sure be appreciated!!

It would probably help if you had a signal injector to find out what stage is causing the problem. You can start and see what the DC and AC voltages are on the tubes. Trouble shooting this or anything else you would start mid way and follow the voltages. Check all voltages from the AVR. Are there any common tubes that work in transmit and receive. Check the respective voltages. If all receive is bad but one band as you can get WWV band, see from the schematic anything common for all the other bands that may be missing. Seems to me you may have a bad switch somewhere that is not used for the WWV band. Brad KB2CHY

I found a service manual for a 520S and you have some voltages to check for. You should also read the service manual because getting WWV band is not a clue to anything other than if it is working well, you are missing voltages somewhere else in the radio. You should probably sit back and read the service manual for more info. Brad KB2CHY

It would probably help if you had a signal injector to find out what stage is causing the problem. You can start and see what the DC and AC voltages are on the tubes. Trouble shooting this or anything else you would start mid way and follow the voltages. Check all voltages from the AVR. Are there any common tubes that work in transmit and receive. Check the respective voltages. If all receive is bad but one band as you can get WWV band, see from the schematic anything common for all the other bands that may be missing. Seems to me you may have a bad switch somewhere that is not used for the WWV band. Brad KB2CHY

Subject: [Bulk] [TS-520_820_530_830] TS-520 No receive No TX?

Hello all, new to the group!
I've been running kenwood rigs since I first got my novice ticket (now General class) 20+ year ago.

Last week I picked up a nice looking Kenwood 520. I was told by the PO it had died during a QSO on 20 meters, It quit both TX and receive.
Got it home and it is dead on all bands in receive. However when you'd push in the WWV button it will receive across that band just fine.
Also noticed at times when you'd push the button in the JJY position it would receive fine for about 2-5 seconds then die, just static.
Also from a cold start it would receive fine (sometimes) for about the same time. Now I cannot get it to receive at all in the JJY position! WWV still

works fine. It has a jumper (solder blob) across the 8 and 9 pins on the vfo plug.

TX is a different story, I'm getting about 70 watts on 80M, 25 on 40M, 10-18 watts or so on 20-10M. Not real worried about the TX side yet, need to get the receive going.

I have cleaned the relays, Checked the WWV/JJY switch, not broken and has continuity in both positions. Loosened and retightened all screws, checked for dead end wires, Checked the voltages on the AVR board for 9 volts and 3.3 volts there ok. Not even sure where to really start looking? Just done a few basic's.

Now I am new to troubleshooting and repair, only armed with a Volt/Ohm meter, A Blown up schematic of the 520, Both the manual and service manual. Would really like to get this old gal working again!
Any help, guidance would sure be appreciated!!

This I believe is you as well on EHam. You have some answers here as well. They tend to say the same as myself, you have some voltages missing. I would check the VFO plug in the rear of the radio and be sure pins 8 and 9 have a good short. This delivers 9 volts to the VFO. Check your schematic, the one I have is pretty bad. I believe your receiver is fine. It seems to be the VFO with the issue. Brad KB2CHY

I found a service manual for a 520S and you have some voltages to check for. You should also read the service manual because getting WWV band is not a clue to anything other than if it is working well, you are missing voltages somewhere else in the radio. You should probably sit back and read the service manual for more info. Brad KB2CHY

One simple thing to check is that "solder blob" across the vfo connector...when there is no VFO, there is a plug-in shorting plug for those pins. If there is no shorting plug, the fix is to make a GOOD connection between those pins...if it is intermittent or high resistance .....anyway, I would remove the blob, replace with a nicely soldered wire connection ...can't hurt, one less thing to worry about..Good Luck ! You came to the right place..

It all depends on the input Z of your DMM. Some are very low (< 1 meg) and some have different values of input Z depending on the voltage range. The lower the input Z the lower the reading you will get. 99% of all DMMs are just fine for measuring most hybrid power supply voltages including RF-1.

If you measure and set RF-1 to 3.3vdc with your DMM it should be very close to the required 3.3vdc. 99% of your power supplies are low impedance sources so your DMM will not pull them down. A DMM is fine for all tube socket pin DC voltages and for all Transistor CBE voltages and all Mosfet DGS voltages.

RF-1 is a power supply voltage. It is derived from the regulated 9vdc on your AVR board. It serves or feeds only two loads (buss or rail) and that is AGC and ALC.

The only two high impedance voltage sources in your radio are the AGC bus and the ALC bus. These are both fed from RF-1 thru 2 meg ohm resistors by design. That means they cannot support any current draw and that a 10 meg DMM and a 11 meg VTVM will pull them down to some degree. You cannot accurately measure them with just about any meter. As long as you understand that you will understand what you are seeing when you try to measure it. You can tell how bad your meter affects the AGC bus by listening to the receiver noise and watching the S-meter when you touch meter probe to agc bus. If receiver noise drops and your S-meter moves up scale you know your meter is the culprit and not a problem with RF-1 or the AGC bus or any of the devices hanging off it.

Just set RF-1 to 3.3vdc using your DMM and definitely replace that missing board screw so that you ensure the entire AVR board ground plane is seeing the chassis ground.

> >
> > I think you said when rig is working you measured approx 2.9vdc at RF-1. You can adjust that with trim pot VR-1 on the AVR board. You want nothing less than 3.3vdc. Receiver will work on 2.9vdc, but not optimum.
> >
> > It sounds like you have a high resistance ground on the AVR board ground plane. This can account for the low RF-1 voltage. I would loosen all the hold down screws and re-tighten (snug) them. No need to install star lock washers. Just dont strip the screws out.
> >
> > Your resistance on the AGC bus of approx 2.7 meg is good. Tells you no shorts on it (like failed meter FET) and no leaky timing caps to pull it down.
> >
> > It is ok to try the temporary 3vdc on the AGC bus when it is at 1.9 or 2.9 vdc. You are simply paralleling dc power supplies like jumpering your car battery with another. It will not hurt anything. No reason to do it if you have consistent 3.3 vdc. I only suggest it when you have low AGC voltage on the bus.
> >
> > Again: First suggest you loosen and tighten AVR board mounting screws and then adjust RF-1 voltage to 3.3vdc and see of receive now acts normal. As I recall there are couple of different AVR board revisions and the ground plane is not continuous around board perimeter so important that all hold down screws make good contact with chassis.

> > > I think my problem might be a loose/cracked connection somewhere, and those are hard to track down. I'm saying this because as I was following your instructions and looking into other measurements following some schematics I have, I flipped the rig and it started working. I then flipped it again and it stopped working, and then tried to flip it one more time and did not work anymore. So I proceeded to make measurements on the transistors on the AF-AVR board, and then, I screwed in place the AF-AVR board again, and now the radio is working again (even after I put it right-side up again). So I'm guessing it's not a component failure but more of a connection failure, right?

OK Jerry that is why I just dont give a yes no answer. I try to give an answer with a fundamental basis behind it. My hope is it will pique your interest and you will take the initiative to crack open a reference book like ARRL handbook or do Google search and read more on the subject. If it bores some folks that is OK. No black boxes for me.

RF engineering handbooks like ARRL and Bill Orr can be trusted, but have to be a little careful about Google sources. If you Google on subject like safety capacitors you can learn all about them.

I am still learning everyday about the how and why of these Kenwood hybrid circuits. Still have lots to learn. Not a day goes by that I dont hit the books or look at a schematic.

Suggest you take notes to refer back to.

> Â
> Several folks have commented about your line filter caps. They are there to shunt rf on the 120VAC line to chassis ground. Sources of RF include portable appliances like mixers and blenders that have brushes and commutators that will arc and place a signal on the 60hz which would then be coupled into your Sig Gen. Three common ways to suppress this in old days. 1.Choke coils in series in the hot and grd leads to transformer primary. 2 A shunt capacitor across the hot and grd leads. and most commonly 3. Capacitors from each line to chassis ground on primary side of your transformer.
>
> Your EICO has No. 3 configuration. If either of these two caps become leaky the chassis can come hot and be a shock hazard. These capacitors see the most severe duty in our radios and test gear because as long the line cord is plugged in to 120vac receptacle the capacitors are energized at all times. This is why new code requires safety capacitor to reduce shock and fire hazard from continuous duty cycle.
>

> So today as Bob has stated you need to replace them with Safety Capacitors. Type X go across the line and Type Y from line to chassis. Easier to just use a universal safety capacitor designated as a type X1/Y2. Can buy these for 10 for $1.00 on Ebay. Check there before buying from Mouser unless you are making an order to Mouser. Capacitance value is not critical. Try to buy as close to values of the current caps. You can remove them and run without them and Sig gen will work just fine, but I would replace them with new Safety Caps.
>
> As for replacing your wax tubular capacitors someone already mentioned using Film capacitors. That is correct but there are large variety of Film caps. Pretty much any of these will work. Plastic/polyester. Metalized polyester. Metalized polypropylene. Polystyrene and Mylar. Polypropylene and polystyrene are better for high frequency applications so I tend to buy and use them. The old wax paper are usually tubular in shape and may even have some "black beauties". Any rectangular brownish ones are likely Mica.
>
> You should easily find Film capacitors at Mouser to replace any paper caps in your 324. Does not have to be Mylar. Mylar is just Dupont trade name.

> >
> > Very good for checking the main plate choke. Most hams would just do a visual. Problem is that they do not know what the design parallel resonance is and where the series resonance holes should be. I have posted all the specs here several times. When I rewind a plate choke I do Dip it, but in practice as long as you use same gauge wire and get back on same number of design turns the series resonant holes should not have shifted. (One pretty close to 24mhz and next strong one at 33 mhz which is no concern).
> >
> > Before digital LCR bridge became common and affordable for the bench would use GDO along with a standard capacitor and standard inductor to calculate unknown inductors and capacitors by placing then in parallel resonant config and finding the Dip and then plug that value into the Resonant Frequency formula and solving to find your unknown capacitor or inductor. Worked pretty well if you were winding your own choke coils or making your own

capacitors

Yes will be a miniature version of the bigger ones in the older style battery chargers. Sounds like selenium is still there so only other reason I can think of for high B+ is higher line voltage we have today?

There should not be a series dropping resistor if the Selenium is still there. So not likely it is source of your high plate voltage. I would still get it out of there.

As I noted earlier the selenium is followed by a pi filter so that is the only resistor you should see close to selenium unless someone has modded this unit.

I used 120 vac as an example in previous response. Looking at the 324 schematic I see it shows the transformer secondary is 110vac so you should measure that voltage. With todays line voltage it may be a little higher. 110 x 1.414 = 155 vdc. 155 - 125 (shown at input of Pi filter) = 30 vdc. That is the drop across the selenium and is a little high if my memory serves right. Havent seen a selenium in a long time.

I dont see what line voltage they are using. Typically in old days would use 117vac. So we cannot tell what the transformer turns ratio is. Maybe it is 1:1 which means if your line voltage at your house is 122 vac you could have 122 x 1.414 = 173 vdc. 173-30 = 143vdc. So you could have 140 to 150 vdc at 1st filter cap.

So measure across the transformer secondary and and then measure at positive terminal of first filter cap.

It sounds to me like you had or have a dirty WWV push button switch. This is a very common problem. By exercising it you got it to work.

The normal position is OFF or OUT. In that position you should have normal ham band receiver coverage. When you push it in you should be able to hear WWV at 10 mhz (zero on the VFO dial). Across the rest of the VFO range may hear some RTTY or CW depending on propagation. It is just provided so you have 10.0 mhz reception to calibrate your Marker with no other coverage intended.

If your 520 is receiving like this then it is OK.

I agree get rid of the solder glob. If you dont plan on using remote VFO just install a small jumper wire on rear of socket with proper soldering.

Try to get some Deoxit and canned air to the WWV/JJY switch and exercise it if you can.

I may have mis-read you post? I also forgot to mention if you have good TX mode then the IF board has to be seeing the VFO signal. VFO signal is applied there and used for both TX and RX mixing. If bad 8/9 solder connection you should have no TIF signal being generated from IF board and no TX.

Also the WWV switch also prevents transmitting on the 10 mhz band. When you push it in to receive 10 mhz it disables the 14vdc supply to the Transmit Mixer on RF board. If you place it in the Out or Normal position and contacts dont make well you could experience loss of normal RX, normal TX, or both.

If you are saying you have good consistent 10.0 mhz reception with WWV button pushed in and no ham band reception with it in the Out or Normal position and you have good TX mode then I would be concerned about your antenna step up transformer L1 on RF board.

Someone mentioned signal injection/signal tracing and that may well be where you are at now.

If fixing 8/9 jumper and cleaning and exercising WWV switch doesnt restore full RX and TX mode I agree you need to reach for RF sig gen.

Terry,

The description I read sounds like a possible diode bridge rectifier.

Does it have 4 terminals on it? How many terminals have wires on them?

Bob:

You may be correct with the arrow symbol on it. When he said like old battery charger I thought of selenium. If it is a bridge rectifier ok to leave it and not install the 1N4007.

Of course if it is a bridge will have less ripple to filter but will still have same 1.4 x xfmr secondary RMS if they didnt include series dropping resistor.

Would sure be nice if we had a real time Skype like feature to help us. What is that they say about a picture!

Terry - reading about what you and the others try to do to help us - in today's world, it shouldn't be too hard for people to take a PICTURE or Picture(s) and e-mail to you. Perhaps you should incorporate that request, when appropriate, to the list of manuals and tools you and the other fellows request.

I certainly think it would have saved a lot of time in this case!

In the early days of PCs, before easy pictures and screen captures, I once wasted several hours because an end-user kept typing in "c\;" and insisting we was typing C slash COLON ! Pictures ARE worth a thousand words...or more!

Jerry,

The following link shows examples of selenium rectifiers. The "s" symbol
on the terminals represents a sine wave and is where the transformer
secondary would be connected. Does your device resemble any of these?

http://4sale.sbszoo.com/diodes.htm

You are correct working on assumptions and misunderstandings and having to ask multiple clarifying questions is certainly not very efficient. A clear close up picture would help in many cases.

42441. Assuming I get my 520 up, what accessories would you consider most needed?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-31 06:25:32 UTC
From: Wes Will
Topic: 42425 Message: 42441

I have the digital readout, with cables. It works, I powered it up separately and checked it with a signal generator. It isn't perfect, perhaps, but it's quite close. (And perhaps it was the signal generator that was off, and the freq. counter was dead on....)

Would the external VFO be of most utility? If so, how much is the going rate on one, and are there any caveats to be aware of, other than the usual ones of not buying a pig in a poke and so on?

(Slightly off-topic for this list, but not so far as to be a rules violation, I think, since it is about a related piece of Ham gear. If I read that part of the list charter incorrectly, I apologize in advance, just say so and it's dropped.)

Using that grid dipper to make a multi-band trapped HF antenna from co-ax cable (a la this article: http://degood.org/coaxtrap/) is proving to be rather a pain in the tuccus. I'm wasting more co-ax than I can afford, and I'd like to end up with an antenna when I'm done.

I've never had a chance to use one of the low-cost (comparatively) "antenna analyzers" that have appeared in the last few years, but they look really --awesome-- and exactly what I need to tune this thing to the right bands. (Instead of where I am at the moment, where it looks like one or more of the traps will likely radiate a lot better in a harmonic for which I am NOT licensed, than in the band for which it is supposedly cut....)

Are the analyzers all they're advertised to be? From the hype, even the MFJ model will do everything imaginable, and walk the dog twice a day, too.

What is the collected wisdom of the group regarding them, which is the best way to go (Buy one on e-Pay and take my chances, build one from a kit, something else entirely?), and does anyone RENT the suckers for a day or two? I don't know that I'd use one that often to make it worth buying, but I'd LOVE to try one on this antenna, to be sure to get it in the middle of the bands.

Inquiring minds want to know! (And don't want to get noticed by Frank and either of the two Charlies.)

TIA.

Date: 2013-05-31 13:12:47 UTC
From: rayosfostoria
Topic: 42425 Message: 42443

Some good points.
I'll remove the solder blob on 8,9 pins and replace it with a good wire jumper, the blob does look milky greyish.
I did clean the wwv switch and checked it with the ohm meter for continuity in both positions, seems it's doing what it should be doing.
Yes very good reception on 10mhz. What little TX output I could get was with the wwv switch in the out position.
One thing I did not do was check the wwv switch for voltages, you mentioned it shuts off the 14 vdc to the rf board. Now if I have power to the switch but nothing through it, could/should I jump the switch and see if anything changes? At least that would eliminate one more thing.

--- In TS-520_820_530_830@yahoogroups.com, "Terry Wagoner" <wagstw46@...> wrote:
>
> I may have mis-read you post? I also forgot to mention if you have good TX mode then the IF board has to be seeing the VFO signal. VFO signal is applied there and used for both TX and RX mixing. If bad 8/9 solder connection you should have no TIF signal being generated from IF board and no TX.
>
> Also the WWV switch also prevents transmitting on the 10 mhz band. When you push it in to receive 10 mhz it disables the 14vdc supply to the Transmit Mixer on RF board. If you place it in the Out or Normal position and contacts dont make well you could experience loss of normal RX, normal TX, or both.
>
> If you are saying you have good consistent 10.0 mhz reception with WWV button pushed in and no ham band reception with it in the Out or Normal position and you have good TX mode then I would be concerned about your antenna step up transformer L1 on RF board.
>
> Someone mentioned signal injection/signal tracing and that may well be where you are at now.

Jerry,

The following link shows examples of selenium rectifiers. The "s" symbol
on the terminals represents a sine wave and is where the transformer
secondary would be connected. Does your device resemble any of these?

http://4sale.sbszoo.com/diodes.htm

Andrew,

  CW filters for the 820(s) are hard to find. Some show up on.....arrrgg EBAY from time to time.
  INRAD/FOX TANGO have them...but tend to be $$.
  Bob Macklin...ke5ftf may have one (he's on this board)
  Crystals for "fixed" operation can be had from International Crystals in Oklahoma City, OK
    they are top notch and really know their stuff!

   I am currently off of HF as I lost my antennas during a recent wind storm...and being partly handicapped
    it's real hard to get on the roof...when the WX sucks...friends don't let friends get on steep roof when wet/windy.
   I have had an 820(s) since about 1984 or so....it's still here

  I'll send you my off-list email addy in a few.

I do have a 520 CW filter I plan to install some day. The problem is that Kenwood did not design the 520 to switch between the filters. You have to cut a connection on the mode switch and add a wire between the mode switch and the filter board.

I don't know how the 820 is wired.

Your best bet is watching eBay.

Are you a contest operator? If not do you really need a CW filter. Where I live the only time a CW filter is needed is on contest days. And I have a SB-301 and a Drake R-4 that solve that problem.

Bob,

I'm sure you are aware of the TS-520/520S/520SE CW filter installation steps that require moving the CW filter select wire on the IF board from the SSB to CW.

You are correct, the TS-520 and TS-520S do not have a CW NARROW/WIDE filter select switch but the TS-520SE does. As you say, the MODE switch does all the filter selections in SSB and CW in the 520 and 520S after the IF board CW filter select wire has been moved from SSB to CW as outlined in the 520 and 520S operator's manual.

There is a wiring changes found on the web that use a toggle switch mounted on the rear panel to control the CW WIDE/NARROW filter selection. I seem to recall there also is a mod that uses the Heater switch, labeled H. SWITCH on the TS-520 and TS-520S models, to act as a CW WIDE/NARROW filter select. Both of these wiring changes/mods for CW WIDE/NARROW filter select will require changes in the MODE switch wiring.

my first response is add an antenna tuner to your radioand the anylyzer is the best 250 i ever spent / i build yagis and such a lot and the mfj 259 lets me tune it on the bench so to speak without putting it high upin the air just sit the reflector on the ground anttenna pointed up and tune awayand i may just try some traps with the dipper portion/make an adaptor with a pl259 and a phono plug and u can plug in different coils for different freqs

Subject: [TS-520_820_530_830] Assuming I get my 520 up, what accessories would you consider most needed?

I have the digital readout, with cables. It works, I powered it up separately and checked it with a signal generator. It isn't perfect, perhaps, but it's quite close. (And perhaps it was the signal generator that was off, and the freq. counter was dead on....)

Would the external VFO be of most utility? If so, how much is the going rate on one, and are there any caveats to be aware of, other than the usual ones of not buying a pig in a poke and so on?

(Slightly off-topic for this list, but not so far as to be a rules violation, I think, since it is about a related piece of Ham gear. If I read that part of the list charter incorrectly, I apologize in advance, just say so and it's dropped.)

Using that grid dipper to make a multi-band trapped HF antenna from co-ax cable (a la this article: http://degood.org/coaxtrap/) is proving to be rather a pain in the tuccus. I'm wasting more co-ax than I can afford, and I'd like to end up with an antenna when I'm done.

I've never had a chance to use one of the low-cost (comparatively) "antenna analyzers" that have appeared in the last few years, but they look really --awesome-- and exactly what I need to tune this thing to the right bands. (Instead of where I am at the moment, where it looks like one or more of the traps will likely radiate a lot better in a harmonic for which I am NOT licensed, than in the band for which it is supposedly cut....)

Are the analyzers all they're advertised to be? From the hype, even the MFJ model will do everything imaginable, and walk the dog twice a day, too.

What is the collected wisdom of the group regarding them, which is the best way to go (Buy one on e-Pay and take my chances, build one from a kit, something else entirely?), and does anyone RENT the suckers for a day or two? I don't know that I'd use one that often to make it worth buying, but I'd LOVE to try one on this antenna, to be sure to get it in the middle of the bands.

Inquiring minds want to know! (And don't want to get noticed by Frank and either of the two Charlies.)

TIA.

Jerry,

I didn't get any pics with your last message since the reflector strips them from messages and I didn't find any at the group site. Try putting the personal e-mail address of a few of those individuals helping you into the "cc" field. That will deliver your message directly to them rather than through the reflector and the attachments should arrive intact.

As for encapsulating selenium rectifiers, I know that the one Collins used in the 516-F was encapsulated but that was a single rectifier (two terminals). Aside from that case, all the others I have encountered have been of the exposed "stack of plates" variety.

I’m going to go ahead and chime in here on the filter discussion. I have TS-530S with both the 270 Hz filter (for CW) and the 1.8Khz filter (for SSB). I’ve found that the 270 Hz filter is very valuable for CW, even under only moderately crowded band conditions. There are many CW QSOs that would have been nearly impossible without the filter.

The 1.8 Khz filter is of only marginal value. Using the IF shift is often more effective than using the filter in crowded SSB conditions.

Mike,

If I install my CW filter in my 520 I will rewire the mode switch the way it should be. If I cannot do that I just won't install the CW filter in my 520.

I'll use my SB-301 or Drake R-4 if I need a sharp CW receiver.

I have never even opened my 520! So I have no idea how bad the problem will be.

Bob,

I'm sure you are aware of the TS-520/520S/520SE CW filter installation steps that require moving the CW filter select wire on the IF board from the SSB to CW.

You are correct, the TS-520 and TS-520S do not have a CW NARROW/WIDE filter select switch but the TS-520SE does. As you say, the MODE switch does all the filter selections in SSB and CW in the 520 and 520S after the IF board CW filter select wire has been moved from SSB to CW as outlined in the 520 and 520S operator's manual.

There is a wiring changes found on the web that use a toggle switch mounted on the rear panel to control the CW WIDE/NARROW filter selection. I seem to recall there also is a mod that uses the Heater switch, labeled H. SWITCH on the TS-520 and TS-520S models, to act as a CW WIDE/NARROW filter select. Both of these wiring changes/mods for CW WIDE/NARROW filter select will require changes in the MODE switch wiring.

I do have a 520 CW filter I plan to install some day. The problem
is that Kenwood did not design the 520 to switch between the filters.
You have to cut a connection on the mode switch and add a wire between
the mode switch and the filter board.

I don't know how the 820 is wired.

Your best bet is watching eBay.

Are you a contest operator? If not do you really need a CW filter.
Where I live the only time a CW filter is needed is on contest days. And
I have a SB-301 and a Drake R-4 that solve that problem.

Subject: Re: [TS-520_820_530_830] Crystals/Filter and general questions about Kenwood TS820s

Andrew,

CW filters for the 820(s) are hard to find. Some show up on.....arrrgg EBAY from time to time.
INRAD/FOX TANGO have them...but tend to be $$.
Bob Macklin...ke5ftf may have one (he's on this board)
Crystals for "fixed" operation can be had from International Crystals in Oklahoma City, OK
they are top notch and really know their stuff!

I am currently off of HF as I lost my antennas during a recent wind storm...and being partly handicapped
it's real hard to get on the roof...when the WX sucks...friends don't let friends get on steep roof when wet/windy.
I have had an 820(s) since about 1984 or so....it's still here

I'll send you my off-list email addy in a few.

42456. Re: TS-520 No receive No TX?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-05-31 17:23:44 UTC
From: Terry Wagoner
Topic: 42425 Message: 42456

Should be no TX capability on 10 mhz. You want no 14 vdc from WWV switch to the RF board N14 terminal with the switch pushed in. With switch pushed in should not be able to tune and load the rig. Should only be able to receive 10 mhz at zero on VFO dial.

With the push button switch in the out position you should have 14 vdc to RF board at the N14 terminal and the antenna coax will now be routed to the NAT terminal instead of the JAT terminal on the RF board for normal ham band receiver coverage.

With push button in the Out or Normal position you should have both RX and TX on the ham bands. If you have neither then suspect lost VFO input to the IF board as others have suggested. If you have either one of the modes then you have VFO signal at IF board and 8/9 is not the problem.

Always get RX going first and then worry about TX. I think that is what you said you were doing.

I may be the only one confused at this point. I believe that you are telling me that with Push button pressed in you have good 10.0 mhz WWV copy and with Push Button out you have no ham band receive?

I think I need to back out and let Brad and others help you. I am mudding the water.

It depends on how serious a CW operator you are as to whether or not you really need a CW filter.

The only time I ever see crowded CW segments is on contest days and I don't work contests.

I’m going to go ahead and chime in here on the filter discussion. I have TS-530S with both the 270 Hz filter (for CW) and the 1.8Khz filter (for SSB). I’ve found that the 270 Hz filter is very valuable for CW, even under only moderately crowded band conditions. There are many CW QSOs that would have been nearly impossible without the filter.

The 1.8 Khz filter is of only marginal value. Using the IF shift is often more effective than using the filter in crowded SSB conditions.

OK the Sarkes/Tarzian No. 50 (for 50 ma) was potted. ST was a big supplier of these units. I forgot about that. It is a selenium that has been potted. Not sure why your B+ is so high unless just line voltage to the primary of your transformer.

If it was my 324 (I have owned and built them) it would be history and 1N4007 would be in its place along with series dropping resistor.

Bob,

I tend to agree with you. My Drake R4C has 4 INRAD filters, 2 for CW (500/250Hz), one for AM (6KHZ), and one for SSB (1.8Khz). I find I don't use the CW filters very much but if I do, it's only when a station is close to my operating frequency. The R4C has a NOTCH adjustment along with a PASSBAND TUNING, similar to Kenwood's IF SHIFT tuning, that helps quite a bit without having to select either of the CW filters.

If I owned a TS-520 or TS-520S and I were going to install a CW filter, I would leave the filter select circuit as it came from the factory and not modify the wiring other than move the CW filter select wire on the IF board as shown in the operator's manual. I don't like modifying a transceiver or any other ham gear for that matter just for "convenience" sake, but that's me.

When I got my New TS520 some other owners suggested I hook that wire to the fixed channel switch position 2 and unhook the wires to the Xtal board so the fixed channel switch could switch the CW filter out and the Wide filter in if you wanted it.
 I decided there was no need for a wide filter on the CW position.
My big old Hallicraftrers SX101a had a narrower filter you could use on CW and I liked it !

I do have a 520 CW filter I plan to install some day. The problem is that Kenwood did not design the 520 to switch between the filters. You have to cut a connection on the mode switch and add a wire between the mode switch and the filter board.

Mike,

The problem with installing the CW filter in a 520 Kenwood's way is it then makes the 520 a CW only unit.

I don't want that.

Somewhere in the tangled thread is a guy who has a filter for his TS520.

I would strongly advise him to go ahead and install it.
It's a simple job and the 520 is a wide open radio to work on compared to the multiple sandwitched boards in a newer radio.
The 80 and 40M CW bands can get crowded in the evenings and not even on contest weekends !
QRM from stations 1 or 2 kHz away can discourage a new to average CW operator !
I grew up with barndoor wide receivers and even I love the narrow filters on CW.
I used a TS520 for nearly 40 years and the first thing I did to it was get the 400 Hz CW filter and install it !!!
 It took about half hour of work, mostly taking out and replacing the cabinet screws !

_____
From: Mike <w5rkl@...>
To: TS-520_820_530_830@yahoogroups.com

I miss read the subject, I read the subject as being a discussion about
the TS-520 CW filter but it seems the discussion is for the 820 CW
filter, sorry, my mistake.
IT SEEMS TO BE A MIXED THREAD WITH SIDE TOPICS.

73
> So is the purpose of the CW filter to narrow the signal as to reject

You dont need an antenna analyzer to tune your traps. As you have found a little tempermental. In old days would use B&W air dux and central lab RF caps. Could then tap down on the inductor or add gimmick capacitor.

With coax traps couple of things you may be fighting. 1. The shunt capacitance per unit foot of the cable may not be as advertised. 2. You need to use a little longer former and add some length to your calculated length. Dont coat the coax turns until you tune the trap. If form is a little long it allows you to spread the turns to tune the trap to resonance.

You should be able to tune them just fine with your GDO if it is paired up with an accurate freq counter.

You can also use a stable RF sig gen and place your trap in series with it and then connect your RF probe and VTVM or DMM at output. A O-scope or RF millivolt meter of course also works great. Use as short a test leads as you can.

Set your RF Sig Gen near your calculated resonant frequency and set the RF output to approx +10dBm or 0.70 millivolts. You need the high level for your rf probe to be able to detect it and drive your meter.

Some fellows use their rig on low power (under 5 watts) and use it as their sig gen.

Now swing your Sig gen frequency up and down frequency looking for lowest voltage dip on your VTVM or DMM or Scope. This is the resonant frequency of your trap. If it is off then spread turns and re-sweep it. Once turns are spread where you want them you will need to secure them in that position. Various ways to pot them.

I would never discourage anyone about building and trying a trap dipole. It is one of the ways to get multiband operation without a tuner. I have had several including a 40 thru 10 using Unadilla/Reyco traps. However, trapped dipoles are not easy to tune, do represent a compromise and do have relatively high wind loading. Of course you are not done after tuning the individual traps. Now you have to understand what the inductance of the trap does to your wire lead lengths on each side of the trap and the end affect. Can be fun!

Only place I want to see them now is in the metal elements of a beam or vertical. Just pointing these things out.

I don't see it that way.

The Kenwood instructions show moving the selection wire from the SSB filter to the CW filter.

That wire is connected to one pole of the MODE switch. That pole has Tune, CW, LSB, and SSB all jumpered together.

So with out rewiring the Mode switch or adding another switch, there is no way to switch between the filters.

This is an original TS-520.

42466. Re: [TS-520_820_530_830] my 520 , what accessories to consider

Topic: 42425 Message: 42466

My $0.02
 Had my TS520 since it was new.
Never had a digi display and got along fine with the internal calibrator, I had to reset it to WWV about once every 3 years.

The salesman at the ham store threw in the VFO520 for free (I did not want it originally) because it would not work with the new TS520S model. He just wanted to get it off his shelf.
I played around with it to make sure it worked and never had occasion to really use it. Sold it for almost the new price a year later.

I never have used a multifunction, fancy, antenna analyzer myself but if you plan on doing a lot of building and experimenting with different antennas I would not say no to an analyzer.
I built a lot of antennas over the last 52 years and only used a basic SWR meter to tune them. Now I could not afford one anyway..
A few years ago I did get the MFJ 207 that is just a self generating SWR meter with an analog dial VFO in it, I believe it cost about $99 and is not made any longer.
It is battery powered and great to use outside when adjusting antennas. In the shack I still use a basic SWR meter to keep track of my antennas' performance.

Subject: [TS-520_820_530_830] Assuming I get my 520 up, what accessories would you consider most needed?

I have the digital readout, with cables.

Would the external VFO be of most utility? If so, how much is the going
rate on one, and are there any caveats to be aware of, other than the
usual ones of not buying a pig in a poke and so on?

Using that grid dipper to make a multi-band trapped HF antenna from
co-ax cable (a la this article: http://degood.org/coaxtrap/) is proving
to be rather a pain in the tuccus.
I've never had a chance to use one of the low-cost (comparatively)
"antenna analyzers" that have appeared in the last few years, but they
look really --awesome--

Are the analyzers all they're advertised to be? From the hype, even the
MFJ model will do everything imaginable, and walk the dog twice a day, too.

What is the collected wisdom of the group regarding them, which is the
best way to go
TIA.

Jerry,

I didn't get any pics with your last message since the reflector strips them from messages and I didn't find any at the group site. Try putting the personal e-mail address of a few of those individuals helping you into the "cc" field. That will deliver your message directly to them rather than through the reflector and the attachments should arrive intact.

As for encapsulating selenium rectifiers, I know that the one Collins used in the 516-F was encapsulated but that was a single rectifier (two terminals). Aside from that case, all the others I have encountered have been of the exposed "stack of plates" variety.

All I can ask is DID U DO THE FILTER INSTALLATION ?
I did it by-the-book and when you are in the CW mode the CW filter is working. In the SSB modes the SSB filter is working !
End of story !

I don't see it that way.

The Kenwood instructions show moving the selection wire from the SSB filter to the CW filter.

That wire is connected to one pole of the MODE switch. That pole has Tune, CW, LSB, and SSB all jumpered together.

So with out rewiring the Mode switch or adding another switch, there is no way to switch between the filters.

This is an original TS-520.

Jerry:

I was sitting here watching golf and thought popped into my head. I think you said you have ordered replacement electrolytic filter caps. Did you need or get some help sizing these or did you get the UF and WVDC listed for C3A and C3B in the EICO manual?

If you ordered 150wvdc units you may want to rethink that. You know you have B+ that approaches or exceeds that. With todays line voltage I think if I saw 150wvdc filter caps and a 1/2 wave rectifier fed from a 117 to 120 vac secondary I would get a little nervous.

If you measure 120vac across secondary then 120 x 1.414 = 170vdc. Under load this will drop some but still too close for comfort for me.
I would want about 20% safety factor so 170 x 1.2 = 204 vdc.

I think I would buy electrolytic filter caps with minimum of 200wvdc rating.

As I previously suggested you should measure the secondary of your power transformer to know for sure what you have and then buy the filter caps.

Maybe Mike can jump in here and give his take. He does a lot of power supply rework.

I think the TS 520 vfo is great. I have a few around the shack. Also have the matching speaker and DG 5. The last vfo I bought off ebay was about $35 shipped. So they are not expensive. Might as well go a head and get the speaker. They also run about $40. Then there is the matching antenna tuner. None of the accessories is a must but neat to have....

I have read the instructions. I have looked at the schematics. I have not opened my TS-520!

The schematics for the 520, 520S, and 520SE show only a single wire connected to the SSB select pin on the IF PCB.

If you move that wire to the CW select pin the CW filter is always selected.

The reason I have not installed the filter is I am not sure I want to try and modify the mode switch to make both filters work.

John and Bob,

I'm sorry Bob but your belief that by installing a CW filter in the 520 or 520S makes them CW only. There's no way I would ever believe a 520 and a 520S models were designed to either be SSB "ONLY" or CW "ONLY" based on the filters installed. That simply makes no sense. Having said that, I can see how you would think that by looking at the 520 and 520S schematics. The schematics for both models are clearly wrong. This would not be the first time I have ever come across errors in schematics and I'm sure it won't be the last.

There are 2 wires that are used to select the filters. One is for CW and the other is for SSB. This can be seen on page 39 in the 520 operator's manual and on page 35 in the 520S operator's manual,

42475. TS-520 Value?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

Topic: 42475 Message: 42475

Anyone got a rough idea what a 520, in good condx, is worth?
Got #2 son here just got his General. Want to get him a rig
where he has to learn how to peak the grids, dip the plates,
etc., like I did. Extra gadgets inside are optional. Hell,
let him learn the same way I did back in 1952 (on a homebrew
rig). Don't want him entering this as a "plug & play" opr.
Would also consider comparible rigs.

Mike,

As I said I have not opened the unit. Maybe this weekend.

The instructions in the 520 manual for installing the CW filter say to move the wire from the SSB pin to the CW pin.

If there really are two wires there must be a jumper somewhere that needs to be removed because without a CW filter the SSB filter is active.

People have mentioned other ways to do the filter selection without modifying the mode switch.

I just looked at the TS-820 schematic and it also shows no connection from the mode switch to the CW filter diode switch network.

At the present time I really do not need the CW filter in my 520 working so I have been reluctant to mess with what seems to be an OK radio,

John and Bob,

I'm sorry Bob but your belief that by installing a CW filter in the 520 or 520S makes them CW only. There's no way I would ever believe a 520 and a 520S models were designed to either be SSB "ONLY" or CW "ONLY" based on the filters installed. That simply makes no sense. Having said that, I can see how you would think that by looking at the 520 and 520S schematics. The schematics for both models are clearly wrong. This would not be the first time I have ever come across errors in schematics and I'm sure it won't be the last.

There are 2 wires that are used to select the filters. One is for CW and the other is for SSB. This can be seen on page 39 in the 520 operator's manual and on page 35 in the 520S operator's manual,

Andrew,

  CW filters for the 820(s) are hard to find. Some show up on.....arrrgg   EBAY from time to time.
   INRAD/FOX TANGO have them...but tend to be $$.
   Bob Macklin...ke5ftf may have one (he's on this board)
   Crystals for "fixed" operation can be had from International Crystals in Oklahoma City, OK
     they are top notch and really know their stuff!

    I am currently off of HF as I lost my antennas during a recent wind storm...and being partly handicapped
     it's real hard to get on the roof...when the WX sucks...friends don't let friends get on steep roof when wet/windy.
    I have had an 820(s) since about 1984 or so....it's still here

   I'll send you my off-list email addy in a few.

RE TS820s

Anyone have suggestions on ....

Where to buy a CW filter?

Where to buy crystals for the fixed frequencies?

Anyone actively using this radio that I may contact directly with some
questions?

Bob,

You're misinterpreting what the manual is saying. There are 2 wires connected to the IF Unit's "SSB" terminal, one is BROWN and the other appears to be WHITE/ORANGE. The manual should have said this but it doesn't which is how I believe you are misunderstanding the filter wiring. The schematic in the manual is also wrong, it only shows "1" wire when there are actually "2" wires.

The manual says to move the "BROWN" wire from the SSB terminal to the CW terminal on the IF UNIT. The manual didn't anything about the other wire connected to the SSB terminal, just move the BROWN wire.

Mike:

You are correct there are two wires. That is why they tell you to move the "brown" one and not just move the wire landed on the SSB post to the CW post. The second wire may be green or wht/grn (perhaps other colors on other production runs?)

As you say no way you are locked in to SSB or CW only. I have stayed out of this one and probably should have as have done far too much jousting and frankly emotionally drained! However, I have your back my friend.

What people dont like is having to use the CW filter all the time when they place the mode switch in CW so there is a popular mod where they install a switch to allow listening to CW with the SSB filter switched in or with the CW filter switched in. I have seen this on a few full filtered TS-520 rigs.

Terry,

Kenwood eliminated the H. Switch (Heater switch) in the 520SE, relabeled it WID/NAR so the operator, in CW mode, could switch the CW filter IN and OUT. This can be done with the 520 and 520S by rewiring the H. Switch or using a SPDT toggle switch mounted on the rear panel.

I agree, it's not a good thing for the CW filter to always be switched in when the MODE switch is set to CW.

Severe thunderstorms with a Torcon of 6 out of 10 for Tornadoes today and/or later on this evening. I'll be glad when this weather mess is over with!

Terry,

I have been waiting to hear from you on this issue. I am surprised to see so many manuals wrong.

I'll try and put my 520 on the bench over the weekend. It does not look like installing the filter is that difficult.

My SB-301 has all three filters. I use it for CW in the USB position unless I really do need the narrow filter.

My Drake R-4a has a variable BW filter. I just set it for the BW needed. Most of the time it is set for USB.

Will the 520 transmit CW in the USB position? My SB-401 will.

Mike:

You are correct there are two wires. That is why they tell you to move the "brown" one and not just move the wire landed on the SSB post to the CW post. The second wire may be green or wht/grn (perhaps other colors on other production runs?)

As you say no way you are locked in to SSB or CW only. I have stayed out of this one and probably should have as have done far too much jousting and frankly emotionally drained! However, I have your back my friend.

What people dont like is having to use the CW filter all the time when they place the mode switch in CW so there is a popular mod where they install a switch to allow listening to CW with the SSB filter switched in or with the CW filter switched in. I have seen this on a few full filtered TS-520 rigs.

have a ts-530s wanting hook up a boom microphone .which would be a good mic with out amplifing it? i am trying to find one everything i have tried makes me to bassie and everyone tells me need one with more highs and less loss . does 600ohm impedance have something to do with it? if i go with a mic with less impedance give me more punch or less punch. just wondering as for frequency what range do i look for as well.....
Thanks KD5UTC and 73S

Well there are plenty of 520 owners who should have helped with this.

I just opened up one here that has no brown wire on SSB post. It has an orange and a green. Orange is typically 14 vdc. It looks like factory routing but no way to tell for sure. No CW filter so I wont spend any time on it.

There are errors across all the hybrids and these are not just typos or translation issues with the various pieces of documentation. As built config can be a problem as well. Have to be careful with wholesale electrolytic change out. I try to document as many as I can in my notes and have large schematics that I mark up.

The TS-820 for some reason is the worst of the lot. Service manual is a beauty and some of the circuit descriptions defy understanding.

The TS-830 last of the line is pretty good but not immune from this problem.

Topic: 37583 Message: 42484

Hi Max,
I have a TS-900 and the RF Gain control is inoperative. The on-line schematics are a bit hard to read. Does your service manual have detailed schematics of the RF Gain control and the RF and IF boards?

Thanks,

Dale W4OP

Terry,

In the three years I have had my 520 I have only used it as a receiver.

I've been thinking about the compromises they have made with transceivers over independent Tx/Rx.

My current thought is the if I do put the CW filter in I can still do coarse tuning in USB and switch to CW if I want to transmit.

I bought the 520 because I was told it had a very nice VFO and used the same conversion system I was used to with the Heath products.

If I have the time over the weekend I will try to take the covers off and look at the IF board.

I have a limited but real 40M dipole antenna. Three days ago I found the W1WA code practice on 20M at 4PM PT. At 7PM I found it on 40M.

Yesterday I got the code practice on 20M at 4PM but no 20M at 7PM.

Today I got the code practice on 20M at 4PM buy it was definitely weaker then the past 2 days.

The signal level on my 520 is comparable to what I see with my SB-301.

Subject: [TS-520_820_530_830] Re: Crystals/Filter for TS-520

Well there are plenty of 520 owners who should have helped with this.

I just opened up one here that has no brown wire on SSB post. It has an orange and a green. Orange is typically 14 vdc. It looks like factory routing but no way to tell for sure. No CW filter so I wont spend any time on it.

There are errors across all the hybrids and these are not just typos or translation issues with the various pieces of documentation. As built config can be a problem as well. Have to be careful with wholesale electrolytic change out. I try to document as many as I can in my notes and have large schematics that I mark up.

The TS-820 for some reason is the worst of the lot. Service manual is a beauty and some of the circuit descriptions defy understanding.

The TS-830 last of the line is pretty good but not immune from this problem.

Yes basically same conversion scheme as Heath and they both copied Collins. I still think the receive audio quality of the TS-520 is hard to beat.

If you have never done a coil pack alignment suggest you read Section 6 of your owners manual. Using the Marker signal you can align the receiver pretty well. You will want to do the RF and IF section.

Note your S-meter levels on all bands before you do Sect 6 and then after you do it to see what improvement you made. Can do a pretty good job of peaking up your receiver performance. Not as good as full alignment with good RF sig gen but pretty close. If you have no means of accurate 50uv signal then just use the Marker and peak it with Drive control on 14.200 and set the S-meter span pot for S9. This will be close.

I have both the operating and service manuals for the TS-900. High resolution replications are taken directly from the original. Had a good review on it on eHam, see http://www.eham.net/reviews/detail/2272 Scroll down to the 1st review dated January 13, 2010.

Thank you for your help Terry!

I adjusted RF-1 to 3.3V and was able to connect the antenna and hear things; no more pegged RF meter. :-)

One thing happened a few times while using the radio tonight, though. I would be tuning or talking to someone (transmitting) and then the radio would go completely silent and the end of the transmission; absolutely no noise and no movement in the RF meter. I tried using a headphone and also external speaker, but I knew that wouldn't help as there was no movement in the RF needle while moving through the band. Transmit would still work, but I would not receive anything. And just to clarify, it would not stay stuck in transmit mode. Then, I would push the ptt different times during the course of 1 to 5 minutes, and then one of those times receive would kick in again and everything would continue to work normally for a while. This happened maybe 3 times within the first hour of use, and after the last one the rig worked fine for the rest of the time I used it tonight (about an hour or so more).

Looking at the troubleshooting section, they made reference to Q3 in the AVR board again, but I had checked that yesterday and it was OK; and because everything starts working again probably means it's not a component failure, right?

Do you have some advice at what I could look for? What could cause it to go silent for a while but then come back alive after a few minutes? Again, it will be hard to find the problem if the radio keeps going back to normal. Should I try something different next time it happens? like not touch it and see if it comes back by itself, to see if the transmitting is what triggers it to get back in motion?

Anyway, thanks again for your patience. ;-)

>
> If you measure and set RF-1 to 3.3vdc with your DMM it should be very close to the required 3.3vdc. 99% of your power supplies are low impedance sources so your DMM will not pull them down. A DMM is fine for all tube socket pin DC voltages and for all Transistor CBE voltages and all Mosfet DGS voltages.
>
> RF-1 is a power supply voltage. It is derived from the regulated 9vdc on your AVR board. It serves or feeds only two loads (buss or rail) and that is AGC and ALC.
>
> The only two high impedance voltage sources in your radio are the AGC bus and the ALC bus. These are both fed from RF-1 thru 2 meg ohm resistors by design. That means they

cannot support any current draw and that a 10 meg DMM and a 11 meg VTVM will pull them down to some degree. You cannot accurately measure them with just about any meter. As long as you understand that you will understand what you are seeing when you try to measure it. You can tell how bad your meter affects the AGC bus by listening to the receiver noise and watching the S-meter when you touch meter probe to agc bus. If receiver noise drops and your S-meter moves up scale you know your meter is the culprit and not a problem with RF-1 or the AGC bus or any of the devices hanging off it.

G'day KD5UTC,

Please leave your name aswell, makes it more friendly to respond. I have 2 530s radios and I use the MC35 and MC50 mic, the MC 50 can be switch simply by changing the plug at the rear of the microphone (red dot is marked on plug)and will give you either 50K or 500ohm. The MC 50 can be removed from its stand and placed into a boom extension.

Subject: [TS-520_820_530_830] microphone question

have a ts-530s wanting hook up a boom microphone .which would be a good mic with out amplifing it? i am trying to find one everything i have tried makes me to bassie and everyone tells me need one with more highs and less loss . does 600ohm impedance have something to do with it? if i go with a mic with less impedance give me more punch or less punch. just wondering as for frequency what range do i look for as well.....
Thanks KD5UTC and 73S

When rig does not come back to receive at end of a transmission is S-meter at Zero or is it upscale or pegged again?

It still sounds like bad Relay. I believe you cleaned both and may have even swapped the Antenna TR relay with the Aux relay?

Next time see if you have any side tone by keying rig in CW mode. If you have side tone volume in the speaker then Audio Output Q3 cannot be bad. Not likely that Q3 is bad.

Two more things to try if the S-meter is not pegged:

First: Try exercising the RF Attenuator push button switch a few times. It is in the RF path after the Ant relay.

2nd: Try turning on the Marker (crystal calibrator) and see if you can hear the 25khz marker signals. Marker signal is applied to the Coil Pack board after the Ant Relay nc contact.

Moving the wire allows the mode switch to select the filter , the way it comes from factory keeps the SSB filter in circuit so there will be a path for the IF signal in the CW mode when only one filter is installed.. You don't need to modify anything else when you install the CW filter !

Subject: Re: [TS-520_820_530_830] Crystals/Filter for TS-520

I have read the instructions. I have looked at the schematics. I have not opened my TS-520!

The schematics for the 520, 520S, and 520SE show only a single wire connected to the SSB select pin on the IF PCB.

If you move that wire to the CW select pin the CW filter is always selected.

The reason I have not installed the filter is I am not sure I want to try and modify the mode switch to make both filters work.

Subject: Re: [TS-520_820_530_830] Crystals/Filter for TS-520

I don't see it that way.

The Kenwood instructions show moving the selection wire from the SSB filter to the CW filter.

That wire is connected to one pole of the MODE switch. That pole has Tune, CW, LSB, and SSB all jumpered together.

So with out rewiring the Mode switch or adding another switch, there is no way to switch between the filters.

This is an original TS-520.

Bob Macklin

From: Bob Macklin
Topic: 42465 Message: 42493

The schematic for the 520 is misleading. The section for the filter selection shows all terminal connected together and a single wire going to the SSB connection on the IF board.

My understanding now is there are actually two wires from the mode switch, both connected to the SSB pin.

Moving the wire allows the mode switch to select the filter , the way it comes from factory keeps the SSB filter in circuit so there will be a path for the IF signal in the CW mode when only one filter is installed.. You don't need to modify anything else when you install the CW filter !

Subject: Re: [TS-520_820_530_830] Crystals/Filter for TS-520

I have read the instructions. I have looked at the schematics. I have not opened my TS-520!

The schematics for the 520, 520S, and 520SE show only a single wire connected to the SSB select pin on the IF PCB.

If you move that wire to the CW select pin the CW filter is always selected.

The reason I have not installed the filter is I am not sure I want to try and modify the mode switch to make both filters work.

42494. RE: [TS-520_820_530_830] microphone question

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-01 10:46:51 UTC
From: AI4WM Bill
Topic: 42482 Message: 42494

The MC-50 has a Cardioid pattern which will increase bass response as you get closer to the microphone. I am not sure about the capsule in the other Kenwood microphones. I have and Electro-Voice MC300 which is also 600 ohm Z. I like the E-V because it has better response than the Kenwood although I get good audio reports using either. Another good microphone is the Shure D444 also is a dual-Z microphone. The other option is for a non directional mic. like the Astatic D-104 with an amplified base. I used one for years with an L-pad on the output to match 600 ohms although it is not required if the output is kept low. The D104 by itself is Hi-Z.

Generally if a microphone impedance is severely mismatched a hi-Z mic on a low-Z input will be tinny and a Lo-Z mic on a Hi-Z input will be very low and or muddy sounding.

If I remember (been a long time since I looked at a manual) correctly the TS-530S has a wide input impedance range like 500 ohm to 50k ohm. If switching your mic. to Hi-Z does not help try speaking farther away (if it is an MC-50 or other directional mic). The other option is to get an omnidirectional mic like the D-104.

G'day KD5UTC,

Please leave your name aswell, makes it more friendly to respond. I have 2 530s radios and I use the MC35 and MC50 mic, the MC 50 can be switch simply by changing the plug at the rear of the microphone (red dot is marked on plug)and will give you either 50K or 500ohm. The MC 50 can be removed from its stand and placed into a boom extension.

Thanks Pete,
I'll pick up the service manual.
A previous owner had bypassed the RF attenuator control for some reason. I repaired that and now the rig is 100%. I have not checked calibration on all the bands yet but it does appear that the 80M het oscillator has aged about 4 KHz- may replace it so I don't have to move the curser so far to the left.
The 900 is one beautiful rig- no plastic trim rings, an extruded front panel and the interior build quality is outstanding- I would say higher than the 599 Twins.

I have both the operating and service manuals for the TS-900. High resolution replications are taken directly from the original. Had a good review on it on eHam, see http://www.eham.net/reviews/detail/2272 Scroll down to the 1st review dated January 13, 2010.

Topic: 42497 Message: 42497

Hi Jim: KE7OAY : I found a lot of helpful information in your Final Cage Repair. My measured capacitance was as follows: Band 28 - 758, Band 24 - 759, Band 21 - 1160, Band 18 - 1160, Band 14 - 1569, Band 10 - 1569, Band 7 - 1831, Band 3.5 - 2630, Band 1.8 - 5040. In doing the check of the load control with one lead of my ohmmeter grounded, I found the rear section, on 24 band to be open,0 ohms,and the same on 21 band, middle section, 0 ohms, on the front section, 14 band i measured 2.3 ohms. With my ohmmeter leads shorted together i have 1.5 ohms. Are there capacitors on the rear band switch, or where should i look next? Thanks Ron KD0KPM

Topic: 42135 Message: 42499

Jerry,

The AUX position is for "receive only". A crystal and resonant tank circuit is required to use the AUX position. The AUX position cannot be used for transmit, ONLY receive.

For example, lets say you want to receive WWV on 10Mhz plus be able to receive the 30 meter band. Since the AUX position requires a crystal, what frequency would the crystal have to be in order to receive WWV on 10Mhz plus the 30 meter band using the AUX position?The crystal frequency would have to be "18.895Mhz".

10 + 8.895 = 18.895Mhz

I have no idea what your electronic and receiver knowledge level is. However, if you lack, for example, the knowledge/understanding of basic receiver operation/theory, I recommend you study basic receiver operation/theory first. In addition, you should study the Circuit Description and block diagram in the 520's manual as well. Without a solid understanding of how receiver's work and how the 520 processes a receive signal, you will have a difficult time understanding how the 520's AUX position, as well as all the other band switch positions, works.

From: Mike
Topic: 42465 Message: 42500

Boband John,

The TS-520/TS-520S schematics are wrong, there are "2" filter select wires, not "1", as the 520/520S schematics show, just as I said before. The TS-520/TS-520S operatormanualsections that shows how to install a CW filter and how to change the filter select wiring (move the BROWN wire from SSB to CW), clearly shows there are "2" wires, not "1". By studying the schematics and understanding how the filters are selected (diode select), it's clear that there has to be "2" wires, not "1", in order to change filter selections when changing modes.

It is also important to note that if the CW filter is permanently removed, for what ever reason, the BROWN wire MUST be moved from the "CW" terminal on the IF board back to the "SSB" terminal on the IF board. If this is not done and a mod has not been performed to add CW/SSB filter select flexibility in CW mode, then the 520/520S will not receive and transmit in CW mode!

This is not the first time, and it won't be the last, that I have found/noticed errors in schematics and had to do further research. A simple but important error I found some time ago in a Heathkit transceiver schematic is in the HW-101 and SB-100. The main schematic of these 2 transceivers shows the transceivers in "transmit", not "receive". The relays in both transceiver's are shown "energized" which puts these transceivers in "transmit". The Circuit Description section schematics, however,show the transceivers in "Receive". The Circuit Description section schematics are correct. Heathkit didn't change this error on the main schematics until the SB-101 transceiver came out. This small but important to know error may seem trivial to some but, like the 520's filter select error on it's schematic, it can create a significant amount of confusion.

I was an electronic design engineer from 1960 to 1998. There was on obsession in the electronic industry to squeeze out any possible cost.

I disagreed with that obsession. I drew my schematics as they really were. In the case of the 520(and it looks like this error alls applies to the 820) I would have connected the two wires to the proper two terminals and then placed a jumper between the two terminals. But this would have been more expensive than the way they did it.

I am beginning to get unimpressed by Kenwood's manufacturing!

Subject: Re: [TS-520_820_530_830] Crystals/Filter for TS-520

Boband John,

The TS-520/TS-520S schematics are wrong, there are "2" filter select wires, not "1", as the 520/520S schematics show, just as I said before. The TS-520/TS-520S operatormanualsections that shows how to install a CW filter and how to change the filter select wiring (move the BROWN wire from SSB to CW), clearly shows there are "2" wires, not "1". By studying the schematics and understanding how the filters are selected (diode select), it's clear that there has to be "2" wires, not "1", in order to change filter selections when changing modes.

It is also important to note that if the CW filter is permanently removed, for what ever reason, the BROWN wire MUST be moved from the "CW" terminal on the IF board back to the "SSB" terminal on the IF board. If this is not done and a mod has not been performed to add CW/SSB filter select flexibility in CW mode, then the 520/520S will not receive and transmit in CW mode!

This is not the first time, and it won't be the last, that I have found/noticed errors in schematics and had to do further research. A simple but important error I found some time ago in a Heathkit transceiver schematic is in the HW-101 and SB-100. The main schematic of these 2 transceivers shows the transceivers in "transmit", not "receive". The relays in both transceiver's are shown "energized" which puts these transceivers in "transmit". The Circuit Description section schematics, however,show the transceivers in "Receive". The Circuit

Description section schematics are correct. Heathkit didn't change this error on the main schematics until the SB-101 transceiver came out. This small but important to know error may seem trivial to some but, like the 520's filter select error on it's schematic, it can create a significant amount of confusion.

Terry,

I tried using the rig again today to contact some ships, and the rig went quiet again for a few seconds and came back to normal, but then again later it went quiet and it has not come back yet, so I took this time to run through the tests you mentioned:

When rig does not come back to receive at end of a transmission the S-meter is at Zero (not pegged). RF gain knob can move the needle.

Yes, I had cleaned both relays and swapped them too. I do hear the relay after I am done transmitting, I just don't hear anything at all when in receive mode.

I do have a side tone when I key the rig in CW mode.

I tried pressing the RF attenuator push botton a few times and nothing changed, still not hearing anything.

I also tried to hear the 25khz calibrator crystal, but I can not hear that one (and I hear it in the past when the rig works properly).

Cesar: This is good info. Here is what it means.

1. S meter at zero and turning RF gain ccw causes it to go up scale tells you that the AGC bus is energized and feeding control voltage to the IF and RF amps so they should have normal gain if rf signal makes it to their gate 1 inputs. This indicates to me that Aux relay you cleaned is OK.

2. Hearing the Side Tone tells you that Audio Amp Q3 is not the problem.

3. Hearing no Marker signal is a clue. As I mentioned the Marker signal doesnt pass thru the Antenna TR relay contacts or the RF attenuator. Look at the schematic and you will see it is coupled into the Coil Pack board at the ANT molex connector (small connector on the Coil Pack board in front of middle air variable VC-2).

Try this:

1.Wiggle ANT molex connector using an insulated tuning stick or probe when receive is dead. If comes alive carefully remove and clean.

2.Touch your finger to VC-2 air variable (middle cap). You will see two unused solder lugs sticking up in air. Touch your finger or use jumper lead and touch/tap the back lug nearer the PA cage and you should hear a noticeable increase in RX background noise.

If background noise peaks it tells you that RF amp, RIF mixer, AGC bus and IF amps all working and problem has to be from RG terminal on RF board back to the ANT terminal on Coil Pack board.

What is in that path is couple of molex connectors and couple of IF traps and the Antenna Step Up Transformer L8. L8 can be hurt, but usually it is not intermittent.

Report findings.

I'm sort of partial to the 599D Twins. I had a TS-900 years ago and next to the Twins, cosmetically, I liked the look of the Twins better. Sold the 900 stuff and kept the Twins. Both rigs worked well but the TS-900 didn't have AM. I believe either the TS-900 or the TS-511 also appeared on the market for a short time as a Frontier Electronics transceiver. Picked up one at a hamfest late 80's or early 90's but it had problems. Didn't have time to work on it so I passed it on at a later hamfest.

Bob:

I dont think they are any worse than any of the others of that era. I would much prefer to troubleshoot a Kenwood than a Yeasu. Some of that due to more likely hacked and abused. Yeasu was so cheap they only used one inter-stage coupling cap between the driver tube and finals and wrecked many finals when the poor quality cap failed and put driver tube plate voltage on the 6146 control grids and the tubes took off.

Plenty of examples of this across other radio brands.

Heath was not immune. I owned and built many of their ham rigs. Undersized bleeder resistors and plate transformers just to mention a couple of design flaws or calcs too close to the margins. Pretty sure bean counters in the loop there somewhere.

I attended a 2 year tech school in the early 70s and when we finished a radio receiver project the instructor picked on me as I was the hot shot who got his working first. He came to my bench and turned receiver on and then picked up pair of dykes and starting snipping out discrete components (mostly capacitors and resistors as I recall) until it got distorted or quit working after about the 5th part was removed. The lesson was we are selling 50,000 units so we dont waste money with nice to have performance. He was getting us ready for the real world when Bean Counters and Designers would cross swords and Bean Counters typically win. I never went on to design.

The other thing is you are thinking like the end user or customer. An old fashioned notion. In nuclear power we call it human factoring. Unfortunately a maintenance worker or tech is never consulted on how something should be designed and installed for ease of access and removal. We used very large pump motor sets on a fixed base/bedplate. The motors (maybe 2500 to 5000 horsepower) are always placed at back of this skid near the wall and the pumps are always on the walkway aisle. The motors are always removed and sent to a large offsite motor rewind shop. The pumps are always rebuilt in place. There is no overhead room and no I-beam for lifting. The motors must be removed with jacking and cribbing (like the pyramid days). Difficult and dangerous work. The Bean Counter and Design Engineers never removed a motor in their lives.

So with Kenwoods and other transceiver designs it is more than prints not matching as built configuration.

I often wished that Kenwood would have used boards on edge cards and use of extender cards to access voltage test points. Would have been really nice, but this method has problems as well.

Hey still beats trying to troubleshoot these modern DSP rigs with boards sandwiched and SMT components. Count me out!

Jerry,

The AUX position is for "receive only". A crystal and resonant tank circuit is required to use the AUX position. The AUX position cannot be used for transmit, ONLY receive.

For example, lets say you want to receive WWV on 10Mhz plus be able to receive the 30 meter band. Since the AUX position requires a crystal, what frequency would the crystal have to be in order to receive WWV on 10Mhz plus the 30 meter band using the AUX position?The crystal frequency would have to be "18.895Mhz".

10 + 8.895 = 18.895Mhz

I have no idea what your electronic and receiver knowledge level is. However, if you lack, for example, the knowledge/understanding of basic receiver operation/theory, I recommend you study basic receiver operation/theory first. In addition, you should study the Circuit Description and block diagram in the 520's manual as well. Without a solid understanding of how receiver's work and how the 520 processes a receive signal, you will have a difficult time understanding how the 520's AUX position, as well as all the other band switch positions, works.

The AUX crystal and tank circuit are located on the TS-520's OSC COIL Unit where all the other HET OSC crystals and coils are located.

After removing the top and bottom covers, turn the 520 upside down, front panel facing you. The OSC COIL Unit board on the left closest to the front panel. The band switch shaft goes through the OSC COIL Unit board and the other 3 boards.

I didn't select 30 meters because I thought you wanted to receive 30 meters in your 520's AUX position. I selected 30 meters and WWV as an "example only" so you can see how the AUX position works, nothing more.

Hi Ron,

In relation to "are there caps on ther rear of the band switch (S22)"? There are 9 capacitors on the rear of this switch, 3 on the rear side near the first valve, which are normally the problem and relativily easy to get to and remove/replace. The other 6 are located on the other side of S22 and are very hard to get to and usually don't cause any problems. Partial disassembly of the PA cage is required and is not very easy or pleasant task, have done this job and can talk you through it if the need arises, but would look at other issues first. Like TIF, SG resistors, molex connectors, TX level diagrams, RF adjust pot on rear panel and SG switch as these are the biggest issues look at the basics first and then move to the more challenging and highly unlikely.

I'm unsure of your PA issue, if you have an issue with running out of capacitance and unable to tune radio on 160,80 and 40 with VR1 and VR2 not tuming in there respective areas, the first caps I would look at are C9 100pf, C10 390pf and C26 22pf. These 3 caps are the ones that are subjected to direct radiated heat from the Valve, what I have found is the capacitors go out of spec or crack, my 390 pf read about 220pf and 100pf read around 50pf. These are RF type 1, high voltage capacitors and cannot be subsituted with a normal cap refer to attached link for reference http://www.qsl.net/i0jx/capacit.html.

Most importantly before venturing into the PA or any other part of the radio, ensure the radio is turned off and disconnected from power source, discharge the HV at least twice as there are lethal voltages that will kill.

If you can repost you question\issue may be able to offer a little more help rather than delving straight into PA first.

Subject: [TS-520_820_530_830] TS-830 final cage

Hi Jim: KE7OAY : I found a lot of helpful information in your Final Cage Repair. My measured capacitance was as follows: Band 28 - 758, Band 24 - 759, Band 21 - 1160, Band 18 - 1160, Band 14 - 1569, Band 10 - 1569, Band 7 - 1831, Band 3.5 - 2630, Band 1.8 - 5040. In doing the check of the load control with one lead of my ohmmeter grounded, I found the rear section, on 24 band to be open,0 ohms,and the same on 21 band, middle section, 0 ohms, on the front section, 14 band i measured 2.3 ohms. With my ohmmeter leads shorted together i have 1.5 ohms. Are there capacitors on the rear band switch, or where should i look next? Thanks Ron KD0KPM

Ron,

Forgot to add, the wafer switches on the RF board can also be a problem, clean these and S22 with deoxit and dry with compressed air. The fingers of the wafer switches can become sloppy and not make contact, it's a matter of just turn you band switch through its range and look at leach wafer to ensure there is good contact, these little fingers also twist out of contact, the other issue the rivets on the wafer switches do crack and can be repaired, look at Ken K4EAA, webpage for photos of that sort of issue

Jerry,

Personally I wouldn't mess with the AUX position especially since it's a
"receive only" position. It never interested me so I left it alone in
the TS-520SE and TS-820S I use to own.

Topic: 42513 Message: 42513

Good evening group,

I tried searching the group but couldn't find what I was looking for. Has anyone had success touching up the outer faceplate on the hybrids? I have a ts-520 with the previous owners name etched on the top of the faceplate. Is there an easy way to fill and repaint? I saw someone a few weeks ago hint that it has been done, but I would like a bit more detail if someone has done it.

hris which RL1 are you talking about? The one on the audio board is soldered in the Antenna relay is usually plugh in, but there are one or two around that have soldered type, have a look from the PA side and you should be able to tell.

Tyler,

I have re-sprayed several front plates for the 530s and 830s series. There are several ways to do it and one takes longer than the other, but if you want to get it back to factory standard, fist thing is before doing anything else is getting a perfect colout match. Good automotive paint suppliers do a fantastic job from my experience.

For large dings and etchings I usually clean the panel first in dish washing detergent then give it a good dry, using XYLs hair dryer. I then use a good quality degreaser. I sand the entire out edge that your indicating using 400 grit and then working to 1200 wet and dry. Once your satisfied you can then get a good automotive filler and fill sand back and fill several more times. Once your happy with the smoothness leave it alone for a couple of months, this usually allows for shinkage as the solvent drys. Once it has completely finished shinking sand a leave 1-2 weeks. Wipe over the entire sanded edge and then take plenty of time to mask the entire front panel. I prefer the blue painters masking tape. Re-wipe the edge and then apply an paint etch, allow to dry and then sand, if it needs a little more you can apply another coat of etch. Allow to dry sand and then rewipe with degreaser and then thinners to match you paint, enamal, acryillic etc. For the edge I use a small airbrush with gravity feed and apply about 5-7 dry coats. Of course a little sanding between each coat. Once I'm happy I then apply 1 wet coat and allow to dry and then give a very light polish. Dont forget there will be a slight colour difference until it drys and then you shouldnt notice anything different. If you need to do the case have a look at WB4HFN.com, very good information. The attached pictures were taken minutes after the final wet coat was applied, 3 weeks later the paint had hardened and you couldnt notice anything different, not even greasy finger marks the controls

Well did some more checks.
Checked Q5 on the IF board for voltages. manual states E=5.1v, C=9.0V, B=5.6v.
But what I had is E=1/2v, C=9.0v,B=7.0v. Changed it out with a replacement and still get the same voltage readings.

So making myself more confused. Having fun and learning.

42520. Re: RE:TS-520 No receive no TX?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

From: Terry Wagoner
Topic: 42519 Message: 42520

How did you get to Q5 on IF board as possible reason for no RX and no TX? No relationship?

Q5 is AGC buffer amp. Small sample of IF from last IF stage Q4 feeds Q5. Q5 feeds the AGC detector diodes D5/D6. These diodes rectify this RF and bias on AGC amp Q6 which is hanging on the AGC bus. With off air signals being detected Q6 acts like a variable resistor and pulls down the AGC bus voltage which reduces the gain of the IF and RF amps so strong signals dont blast your ears.

To measure CBE voltages on any of the IF or RF amps I would have rig on dummy load so off air signals cant cause any AGC action.

If Q5 is bad about worse that can happen is no S-meter action, but rig should still receive unless S-meter is pegged.

Usually with no RX and no TX people start by making a visual, poking and prodding and removing and cleaning both relays and exercising JJY/WWV push button and checking 8/9 jumper on rear of rig.

After you exhaust those things I would start with low voltage power supply voltages at AVR board and make sure have good RF-1 and 9vdc regulated. Then turn on Marker and see if you can hear it. I would focus on getting Rx back first although it could be something common to RX and TX and VFO comes to mind.

42521. KENWOOD HYBRID USER NET (June 2nd, update)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-02 18:38:12 UTC
From: mvgilger
Topic: 42521 Message: 42521

The Saturday's net on 40 meter had only 1 stations checking in with very poor band conditions. Out of all stations checking in, there was:

1 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
0 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 9 stations checking in under very poor band conditions. We had 9 new check-in, KD0TGD, AE6OR, and VE4AMN.

Out of those, there was:

2 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
1 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39

April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 45, Sunday's total = 50
June 2013, Saturday's net total = 1, Sunday's total = 9 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Topic: 42521 Message: 42522

Don't expect the band conditions to improve unless we get a double peak to the solar cycle.

Are there any West Coast people on these nets?

Subject: [TS-520_820_530_830] KENWOOD HYBRID USER NET (June 2nd, update)

The Saturday's net on 40 meter had only 1 stations checking in with very poor band conditions. Out of all stations checking in, there was:

1 running TS-520(x)
0 running TS-530(x)
0 running TS-820(x)
0 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 9 stations checking in under very poor band conditions. We had 9 new check-in, KD0TGD, AE6OR, and VE4AMN.

Out of those, there was:

2 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
1 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 - Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39
April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 45, Sunday's total = 50
June 2013, Saturday's net total = 1, Sunday's total = 9 (Month to date)

Found that fix listed on a web site.
Also found mention to Q4 and Q5 on the RF board. Checked voltages on both. Both have low voltages except for the D leg, both show correct voltages per manual on leg D.
Kind of at a standstill for the moment.

OK you are looking at one of those so called "service bulletins" that has long list of one line entries. They have you hopscotching around your radio. Many if not all of these one line entries are anecdotal and useless as they were for one off events.

You never want to start replacing active devices. They seldom fail. I think only bad Q5 RF amp mosfets I ever saw were due to ESD or inadvertent transmit RF and certainly a bad Q5 RF amp mosfet isnt going to cause no TX output. The list you are looking at apparently has a one line entry that says if you have no receive you should replace the RF amp mosfet and/or the Het Mixer. That is silliness and shot gun approach.

If you have done the things I suggested in my first response and no luck then time to start troubleshooting.

Normally that consist of signal injection and signal tracing and when you find area where you are missing the "goes ins" and/or "goes out" then you can break out your DMM and take CBE or DSG voltages at the active devices.

If you care to restate the no RX symptoms in a detailed problem statement maybe I or someone else can direct you where to start logically and systematically.

Not trying to spoil your fun just trying to help you.

By the way having normal voltage on the Drains of Q4 and Q5 tells you that you have good 14vdc at the RF board N14 terminal post with the WWV push button in the out position. Is that how you took the DSG readings on these devices?

Do you have a RF signal generator?

If so one last shot gun. Set sig gen for 5 mhz output and if you have calibrated output level set the output to approx +13dBm. If no calibrated output level then just turn the switched step to High and variable output as high as you can. Now connect signal to VFO terminal post on IF board (near front left edge of board). See if rig comes alive. If it does you know VFO signal isnt there. It is required for both RX and TX mixer operation. May have to swing the sig gen frequency between 5 and 6 mhz if you have no freq counter to verify accuracy of the dial.

Hi Chris,

Never seen a plug in type on the Audio board, Terry, Mike or Gordon may have seen more? When you go to change out the relay be careful removing the molex connectors and even more careful when de-soldering and soldering back in. Whilst you have the board out, check the molex connectors on the foil side under high magnification for foil cracks and dry joints,

It appears you are referring to the relay on the 830 audio board. If so
then that relay is not in a socket, it's soldered to the AF Unit board.
Don't try cleaning it because any cleaning success will be short lived.
If this relay is found to be the source of your problem, replace it. See
Ken, K4EAA, website link below for details on ordering a replacement.

Hi Guys, does anybody have a remedy to fix a 520 vfo that has some dead spots? When I get higher up on the bands I have to play with the knob to get the sound to come back on. acts just like a dirty pot but is there a fix to actually make things right? Thanks for any help

This is a common problem, the fix involves cleaning grounding fingers contacting against a rotating shaft.

Subject: [TS-520_820_530_830] 520 vfo issues

Hi Guys, does anybody have a remedy to fix a 520 vfo that has some dead spots? When I get higher up on the bands I have to play with the knob to get the sound to come back on. acts just like a dirty pot but is there a fix to actually make things right? Thanks for any help

Hi All,

have a problem in a IF board, had to replace Q1 & Q2 (3SK35gr & 3SK41) because not tif mixing signal present in, after replace measure in TP1 (IF board midle q1,q2) and the signal starting with noise 3.4 mhz and 360mv-vpp and this going to die in a few seconds similar to a discharge cap, the same problem in a TIF with the diference 8.5mhz(the mixing car & vfo it's ok) this singal checked in other circuit any idea?

To measure TP-1 signal level make sure you have Screen Grid switch off. Mode switch in CW mode. Key the rig with Car Level Pot advanced and Drive Control peaked for maximum ALC reading on the meter.

I think you are saying at TP-1 you see approx 360 mv P-P, but it decays off like a capacitor discharging. 360mv is a good level and 3.39mhz is correct frequency. The 8.8mhz TIF signal will be mixed by Q2 and the TIF signal at the TIF terminal post on IF board will be approx 100mv P-P. If signal at TP-1 is decaying then signal at TIF post will do likewise.

What is the S-meter doing as the signal decays? Is it slowly falling down scale?

It sounds like you are losing ALC to Gate 2 of Q1. Need at least a 11 meg ohm VTVM or DMM to measure the AGL terminal post on IF board and see what the ALC control rail voltage is doing. Your meter will pull it down to around 2 volts, but should hold at that level.

You can connect a temporary +3vdc to the AGL terminal on the IF board and see if signal level at TP-1 stays at 360mv P-P.

If AGL voltage is decaying then pull your Aux Relay and clean the contacts as a first step.

Terry K9TW

Have you verified the rear panel jumper plug or jumper wire is in placed between pins 8 and 9 on the 520's rear panel VFO socket? Don't just look at it, check it to be sure the jumper is making good contact. A jumper wire can be shoved into the pins but not make contact. If the jumper is not in place and making good contact then the internal VFO will not receive power which results in the 520 having no transmit and not receive. The jumper plug or jumper wire, both perform the same function, provides a path for the 9VDC supply to power the VFO. If the jumper plug or jumper wire is missing or not making contact with pins 8 and 9 then the VFO will NOT receive power and won't provide the necessary signal to the IF Unit board and, again, receive and transmit won't work.

I wouldn't jump to any conclusions. 20 meters is rocking right now as I type (10:44 PM EDT), with coast to coast signals, and to Europe, and to Australia and New Zealand. We've had some disturbed conditions over the last 48 hours but whether we hit the sun spot peak already is still in the hands of the jury. I was on 20 this morning from 9:30 to 11 EDT and worked about a dozen stations in Eastern and Western Europe. Last night (Saturday) I worked 5 stations in Australia. And, 6 meters has been open all day, every day, somewhere in the U. S. Right now, 6 is open from the West Coast to all across the southern states to Florida and to Mexico. You need to get out more Bob. Hi

Yes, usually 3-4 check in on the Sunday 20 meter
net. Today was excellent to the west cost.

Mike
When I first recieved the 520 it was missing the 9 pin plug, that was my first thought as to why it was not working (I have a TS 700SP, same deal with the 9 pin plug). However when I removed the cabinet I checked the plug and it had a solder blob placed between 8 and 9. Through advice on here I removed the blob, replaced with a soldered in wire jumper and checked the voltage, 9 volts. Some I'm quite sure thats not the problem.

Yes one of the kenwood service bulletins,I printed it out.

I checked the N14 post on the rf board as you suggested, yes 14 volts in the out position.

Receive symtoms are as follows: With the WWV button pushed in it will receive wwv and the whole 30 Meter band great, will do it all day.

Now if you have the WWV button in the out position you get static noise, the noise best way I can describe it, is like your listening to a quite spot on a band, but has a little lower volume. Now on occasion it will recieve normaly once you set the switch (JJY) out but only for a few seconds but it's sporadic at best and I could not get it to do that all weekend. I have cleaned, checked, cleaned and tested the wwv switch till my fingers hurt (hi hi). I have even ran jumpers across the switch terminals to see if it would recieve, wich would tell me if the switch was bad, no differance.

Trust me your not spoiling anything! I need the help! My TS-450 was easy to fix, swap out a board and it works great. This one is my first real major repair.

I think only bad Q5 RF amp mosfets I ever saw were due to ESD or inadvertent transmit RF and certainly a bad Q5 RF amp mosfet isnt going to cause no TX output. The list you are looking at apparently has a one line entry that says if you have no receive you should replace the RF amp mosfet and/or the Het Mixer. That is silliness and shot gun approach.

Wish I had one! Just have a Volt/ohm meter and a picky freq counter!

> Do you have a RF signal generator?
>
> If so one last shot gun. Set sig gen for 5 mhz output and if you have calibrated output level set the output to approx +13dBm. If no calibrated output level then just turn the switched step to High and variable output as high as you can. Now connect signal to VFO terminal post on IF board (near front left edge of board). See if rig comes alive. If it does you know VFO signal isnt there. It is required for both RX and TX mixer operation. May have to swing the sig gen frequency between 5 and 6 mhz if you have no freq counter to verify accuracy of the dial.

OK-- Well as we previously discussed if you have good and consistent 10 mhz WWV then you have to have VFO signal at IF board. Still sounds like N14 is not coming hot or Q5 and/or Q4 are not getting Drain voltage.

They are both in sockets so could remove and re-insert being careful to orient correctly. They have a tab on them to help with this. Q4 tab will face the front panel and Q5 tab will point to the VFO. Could just wiggle them around.

With a small sharp probe tip you can use your VOM to measure the Drain lead at the socket on each to make sure they are getting 14vdc.

Easier to just measure the Source voltage by touching probe to the device metal can. This may be easier for you and if they are turned on should see approx 2.3vdc on Q5 and 1.6vdc on Q4 from can to chassis ground.

If no calibrated output level then just turn the switched step to High and variable output as high as you can. Now connect signal to VFO terminal post on IF board (near front left edge of board). See if rig comes alive. If it does you know VFO signal isnt there. It is required for both RX and TX mixer operation. May have to swing the sig gen frequency between 5 and 6 mhz if you have no freq counter to verify accuracy of the dial.

Steve: I have said it many times be very careful with these so called "service bulletins" especially No. 21. If it was really originated by Kenwood factory engineers, approved by them, and issued by them then it was when they landed on our shores and working out of a garage in LA!

You can go line by line and see problems with just about all entries. Anyone can produce a service bulletin that list each IF amp mosfet and each RF amp mosfet as the reason for No Receive condition. What sane person would replace all the gain controlled devices every time they had no receive?

I think No. 21 is just anecdotal collection from owners and perhaps from Techs at authorized Kenwood dealers. Very different than from Kenwood.

Here is just one example under the Transmit list:

18. No bias: 10 ohm cathode resistors burned in final VOX.

What it is trying to say is this.....If you have no resting or idle or quiescent plate current with the rig keyed then check for open 10 ohm cathode resistors on the final board. Did you get that out of it?

No engineer or knowledgeable tech would say rig has no "No Bias" if they meant No Idle Current. When I see that I would ask do you mean cutoff bias voltage or operating bias voltage or both are missing? I would be measuring bias voltage at the control grid of the tube. Of course if No Bias then you would have lots of plate current until the tube failed.

So my advise to you is DO NOT implement any of these line items unless you understand what they are saying and it makes technical sense to you that it could be source of your problem.

I can write a No. 21 for a lawn mower engine.

"Engine wont start"
1. Replace the spark plug
2. Replace the fuel filter
3. Replace fly wheel key
4. Replace fuel bowel needle and seat
5. Replace magneto coil
6. Replace coil wire
7. Replace voltage regulator module
8. Replace.....You get the idea

No engine tech would ever follow this No 21 "service bulletin". Well maybe unscrupulous dealer who likes to sell parts and has no qualified techs might if the customer was willing to pay for parts they dont need.

> Now if you have the WWV button in the out position you get static noise, the noise best way I can describe it, is like your listening to a quite spot on a band, but has a little lower volume. Now on occasion it will recieve normaly once you set the switch (JJY) out but only for a few seconds but it's sporadic at best and I could not get it to do that all weekend. I have cleaned, checked, cleaned and tested the wwv switch till my fingers hurt (hi hi). I have even ran jumpers across the switch terminals to see if it would recieve, wich would tell me if the switch was bad, no differance.

I picked up a 520 in less than operating condition. The strangest thing, three of the trim pots had lost their wipers. Two were on the AVR board. I replaced all three, adjusted the voltages and viola, the rig works. But, there seems to be a mod that I can not trace. There is a 1K trim pot with a 3.3k resistor in series mounted on a terminal strip next to the CW filter. There is a blue wire going under the 100KC calibrator and a red wire going somewhere underneath in the front. I checked several pictures in the manual and I do not see this teminal strip. Does anyone know what this may be for? My TS-520se does not have this.

It is not a mod. You have early version. It provides bias voltage for Q2 TIF amp mosfet on the IF board via TBL. On later versions these components are incorporated on the RF board.

Look at the schematic in your Owners Operating manual and see if the pot and resistor appear just left of the RF board.

Do not remove these components.

Your SE has same parts mounted on the RF board.

Some owners do remove the terminal strip and trim pot and resistor and replace it by tack soldering a single 3.3k resistor between the TBL and RLT terminal posts on the RF board.

This is OK as it retains the +1.8vdc bias voltage you need to turn on the TIF amp in TX mode and the -5.6vdc or so bias voltage you need to turn off the TIF amp in RX mode.

You can tell if your external config is working properly by measuring IF board TBL post voltages in RX and TX mode.

Terry
OK checked Q4 for orientation,tab is facing front panel, touching the top of Q4 I have 1.6 volts this is only in the JJY position, in the WWV position, nothing.
Q5 it's tab is facing the driver tube, top of can measures 10 volts in the JJY position and nothing in the WWV position.
So oviously Q5 is oriented wrong, should I put the tab facing the vfo and see what happens?? I'm guessing this ones (Q5 is toast) bad just due to wrong orientation and the high voltage??

Side note: I bought this rig locally from a gentleman who had said it just died during a qso on 20 meters, was told that the day I bought it. Next day I talked with him on 2 meters, he told me it's been down for 2 months and that he had messed with it a bit trying to get it to work, Kind of sounds like an ebay deal??? I havent messed with the rf board yet other than tightening screws on the board.

OK having 1.6vdc source voltage on Q4 in JJY proves it is turned on and as you know you have good 10 mhz receive.

Having zero vdc on Q4 source in Normal position of course means it is not turned on. Reasons for not turning on include no 14vdc drain voltage, no bias voltage on Gate 1. Really best to measure all voltages at the leads of Q4. You can do that with a small probe carefully at the socket with Q4 inserted or you can pull Q4 and measure at the socket.

Can take same measurements at Q5. If you are using a VOM you will get a low reading on Gate 2 but D,G1, and S should be close to values listed in your manual. Gate 2 is AGC and your meter will pull it down.

Q5 could have been replaced with a sub thus the different orientation of the tab or maybe my recollection is flawed. If Q5 was bad you would not be able to get the momentary receive that you report with WWV push button in Normal position. Mosfets typically either open or shorted and dont heal themselves. Always look for normal DSG RX and TX dc voltages before suspecting bad mosfet and replacing. Of course easy to swap in your TS520. A 40673 and 3N211 are good subs as well as NTE 222. If you have a sub can try it but make sure leads oriented correctly. When you measure voltages at socket make a drawing so you can id DSG1G2.

Momentary good HF receive sounds more like loose connection, bad wire wrap or dirty contact. If N14 voltage is there and stays there then not likely that Q4 and Q5 are not seeing Drain voltage. More likely they are not getting their dc operating bias. Q4 and Q5 get there operating bias voltage from RLR on RF board, from NC aux relay contact, from 9vdc on AVR board. If that NC contact on Aux Relay is bad then you could have momentary good HF receive.

Remove Aux Relay and clean contacts. Can try swapping with Antenna TR relay. Can also monitor voltage at RLR terminal on RF board and see if have good steady 9vdc when you key rig on and off.

Just a quick reminder with Q5 pulled from socket and taking dc voltages you will have 0 (Zero) vdc on the Source pin as you need current flow thru the source resistor to have any voltage. Also Drain voltage will be high and close to 14vdc supply voltage. Gate 1 will be somewhere around +1.8vdc.

Gate 2 voltages will be:
1. With VOM or any low Z multimeter approx +1.3 vdc and S-meter nearly pegged full scale

2. With 11 meg VTVM or other high Z multimeter approx +2.5vdc and S-meter near S4 to S5.

Looking straight down on socket Source is upper left, Drain is lower left, Gate 1 is upper right, and Gate 2 is lower right.

Lastly do not plug and unplug Q4 and Q5 in and out of sockets with power on and dont handle the bare leads.

Scotts Electronic Parts who sells Crystal Radio parts use to carry NOS 40673 devices. Not cheap but work well.

Thank you. Good information. The pot in my rig was measured at 1K and is wired as a variable resistor (wiper connected to one side of the pot) and is therefore a two terminal device. The schematic shows VR3 near the RF board as 10K and a three terminal pot.

I will measure the bias on Q2 and see if adusting the pot on my rig changes the bias voltages. Thanks for the voltage readings, that will help alot.

the trim pots had lost their wipers. Two were on the AVR board. I replaced all three, adjusted the voltages and viola, the rig works. But, there seems to be a mod that I can not trace. There is a 1K trim pot with a 3.3k resistor in series mounted on a terminal strip next to the CW filter. There is a blue wire going under the 100KC calibrator and a red wire going somewhere underneath in the front. I checked several pictures in the manual and I do not see this teminal strip. Does anyone know what this may be for? My TS-520se does not have this.

There is a Heathkit PK-3 RF Probe listed on Ebay. He is wants $49 for it which is a little stiff, but that includes shipping which is just about $10.00 anymore. It appears to be in good physical condition?

This probe will allow you to measure RF drive levels at the Plate of the 12BY7A Driver Tube and at the Control Grids of the 6146 finals.

About the worse that can happen is that the builder did not install 3 of the 1N191 diodes. It was a builder option. These diodes are pricey when you can find them. You do not need a gold bond point contact diode. You can use 3 1N34, 1N60, OA91 etc. So if you buy need to open it up and see how many diodes installed. Can just slide the back black plastic strain relief back and shine flashlite in to see the diodes.

Pretty hard to homebrew a RF probe with this nice a packaging. It has a 1/4 phone plug on end of shielded test lead so that it mates with Heath VTVM. Could be changed for other brand of meters.

You are looking at VR-3 RF Gain pot which tells me you have the wrong rev Operating Manual for TBL config on your rig. Go to Gordons website and download the TS520 operating manual and look at Fig 38 Main Schematic and you will see the components I mentioned that I believe is what you are seeing at your IF board.

It is possible there are more than one combinations of trim pot and resistors. I have only seen one.

Gordons schematic will show VR-1 as a 5k pot. The pot installed on TS-520S and SE RF board is a 1k. As I mentioned a resistance value of approx 3.3k to 3.9k ohms between RLT and TBL is just about right.

Just go to TBL terminal on IF board and measure voltage in RX and TX modes as I noted previously. If you can get on Gate 2 of Q2 can measure there as well.

Jerry:

Are you saying the transformer secondary is 145vac? I am surprised if that is the case. I would have guessed ratio was close to 1:1. Need to measure secondary AC then can calculate what the dc output will be.

Ordinarily when you replace a selenium with a silicon you end up placing somewhere around a 100 to 200 ohm resistor in series with the silicon diode down stream between it and the filter. This is because a good selenium normally has around 5 volts drop across it and the silicon about 0.7 drop so the dc output from the silicon will be approx 4 to 5 volts higher being applied to your Pi-filter. If you know the Ma load current can calculate the value of the needed series resistor but usually just temporarily try values.

You can just swap out for the silicon and install the new filter caps and see what happens to the B+ line. If it is only 4 or 5 volts more than shown on schematic I would not worry about it. Part of reason that you may currently have such high voltage is that seleniums do age and when they do the output voltage may go up. So with the silicon in its place the new output voltage may not be anywhere near what you are seeing now.

I think I would install the diode and filter caps and measure the tube anode voltage at the socket and decide if a series resistor is needed based on what you find.

I would not change the value of your Pi Filter resistor. I would measure it as likely carbon and may have drifted high. Its value is chosen for correct time constant for filtering. It is poor mans choke.

Topic: 42556 Message: 42556

I just received the above radio in which the mail service was not to kind with the shipment. When I unpacked the unit and tried to check the receive of the radio, it kept blowing fuses. I checked the fuses and plugs and found numerous loose connections. Once I made sure everything was seated, the rx was good. Now I am trying to tune the transmitter and am checking the plate idling current. The current will not exceed 10 ma's and that's with the bias all the way up. I have found numerous articles about excessive current and no current but not anything about low current.

I think the heater is kicking on as I see the meter lighting dim a little when switching it on. When the heater is on, should I feel warmth on the case as I wonder if it is running correctly? Could it be something else that might be loose?

Something a little different, I have read Walt's article on discharging the units voltage, I wonder if there is a picture out there demonstrating this procedure?

Thanks in advance and 73 .

Eric

OK then if you assume that your load current is 50 ma (max rating of the Selenium)and you want to drop 140vdc to 110vdc then 30vdc/.050 = 600 ohms. Wattage rating = I squared x R = .050 x .050 x 600 = 1.5 watts. I think I would start with a 470 ohm 2 watt resistor after the new Silicon diode.

Of course you could measure the B+ current.

Maybe some one else with experience replacing a selenium can help you size your series dropping resistor.

Folks

My TS-830S audio just stopped one night. The radio appears to work correctly, i.e. tunes, calibrate peaks, etc. but I get no audio with the AGC in Fast or Slow. If I turn the AGC Off, I get audio. Not perfect audio, but audio as one would expect with no AGC.

Anyone have any suggestions as to where to start to look?

Thanks,

Bill

Eric:

There is no "heater" in the radio that you will feel any warmth from. Heater is a term for the tube filaments. When you turn it on it supplies AC voltage to the filaments and they heat the cathodes so the tubes will have electron emission. If you had covers off you could see the glow of the filaments or heaters inside the glass envelopes of the three vacuum tubes (12BY7A driver tube and 6146 final tubes). The tubes do get hot but not hot enough for you to feel much heat on the cabinet. The cooling fan on rear of rig pulls air thru the PA (power amplifier) metal gage to help cool the final tubes.

It is very wise not to remove covers or work inside the radio if you are uncomfortable doing so. However, it appears you recognize there is dangerous high voltage and you need to make sure the HV filter caps are discharged before you work inside the radio. I dont know of any pictures. Since rig was so roughly treated you do need to open up and do a visual inspection and especially make sure that all three tubes remain seated in their sockets. Here is what I would do:

1. Unplug the rig and let it set for 1/2 hour or so that the bleeder resistors on the HV filter caps have chance to discharge them.

2. Remove the top and button covers of the radio and be careful to unplug the yellow cable from the speaker.

3. You should see the 12BY7A tube on the RF board. Make sure it is seated in its socket. It should have a black metal shield can on it.

4. Remove the PA cage cover (top right rear). You will see the two 6146 final tubes and between them the RF Plate Choke.

5. The top of this plate choke is where you need to place a short to ground to ensure there is no voltage remaining in the filter caps. With rig turned on there will be 900vdc at this point and enough current behind it to kill you. Never point,touch or drop anything in the PA cage with rig energized. Some folks will use a screw driver to short from top of the plate choke to the metal shield. That is poor practice. Your radio is not a welder. You dont want to transfer any metal and leave arc and pit marks. Best way is to make a short jumper lead with good insulated test lead wire and place about a 4.7k ohm resistor in series with it. Resistor value isnt too critical just dont make it too high a value. Can get by with no resistor if you leave rig unplugged long enough. Place alligator clips on each end. Connect one clip to chassis ground and hold other end on top of plate choke. Dont just tap it but actually connect it there for a while. Now you have the HV filter caps discharged, but be aware there are other lower voltage filter caps (300 vdc) that can still have voltage on them for screen supplies etc so dont bare hand touch anything on the rectifier board or on RF board near base of Driver tube.

6. Now that you have 900 vdc B+ discharged it is safe to get a hold of each 6146 final tube and make sure they are seated in their sockets and that the anode caps are firmly seated on top of the tubes and that the parasitic suppressors from top of plate choke to anode caps

are soldered well. Just give gentle tug on the leads. Sometimes the solder sublimates (dull grey looking) and the connections to the anodes are not good. While there see what kind of finals you have ie 6146B or 6146W and both tubes should be same designator.

7.Note the filter caps standing by the Power Transformer. Are they tall black original ones?

8. Flip rig over and look at filter caps rupture vents to see if there is any swelling or leakage. May see convex curvature of the rubber vent and/or white powdery deposits around the vents. If really bad may see some brown/black tar like leakage. If caps have been changed out they will be short black or blue units.

9. As to 10 ma resting plate current what test equipment do you have?

What is the S-meter doing in Slow or Fast when you have no Audio?

Bill:

I tried to respond to your off list response and got message that your mail box was exceeded. I dont need any typing practice!

Do you have cw side tone with AGC in fast or slow?

Reason I asked about S-meter is if you do not have the Product Detector carrier nulled the carrier can leak back to the AGC detector diodes thru L12 and they see this as the same as a very strong off air signal and bias on Q10 AGC amp transistor and can saturate it and place -6vdc on the AGC bus and shut done the receiver. When Q10 is turned on reduces receiver gain and it drives the S-meter up scale.

AGC in Off turns off Q10. Sometimes the null capacitor TC-1 can be set on the edge and it can just drift off and cause this problem. If S-meter is at Zero in fast or slow then the AGC bus isnt being shut down by Q10. So carrier null not the problem.

No connection between AGC and Audio board that I am aware of. Will look at schematic.

Other thing you can do is with AGC on fast or slow inject some audio at the Product Detector output on the IF board at Conn 11 Pin 1 and see if you hear it.

As you mentioned with AGC off audio distorts on strong signals so you need to control by riding the RF gain pot. Can get normal sounding audio that way so rig is usable. Many Ops prefer to run that way especially CW Ops. Maybe running this way is old timers technique?

Eric:

I forgot to ask do you have the screen grid switch on back of rig in the on position? Should have no resting plate current if it is off but need to check it and cycle it couple of times.

Also, reason I asked about test gear is if you have a decent multimeter (DMM or VTVM). So that you can measure:

1. Cathode resistors ohmic value on final board
2. Operating and cutoff -dc bias voltage at 6146 final tube socket
3. Screen grid voltage at 6146 final tube socket

You can also place panel meter in HV position and read B+ but remember all this tells you is the power supply is working and you havent lost a HV filter cap. It does not tell you if any B+ on the 6146 anodes.

Dont try to measure the 900vdc at tube anode caps until we discuss how to do this safely.

I also forgot to mention when you are performing the visual inspection in the PA cage to make sure the finals arent broken and still seated in sockets to look at the Plate choke to see if it has been overheated.

Lastly ,only if you are comfortable taking these resistance and voltage readings safely.

If you had covers off you could see the glow of the filaments or heaters inside the glass envelopes of the three vacuum tubes (12BY7A driver tube and 6146 final tubes). The tubes do get hot but not hot enough for you to feel much heat on the cabinet. The cooling fan on rear of rig pulls air thru the PA (power amplifier) metal gage to help cool the final tubes.
>
> It is very wise not to remove covers or work inside the radio if you are uncomfortable doing so. However, it appears you recognize there is dangerous high voltage and you need to make sure the HV filter caps are discharged before you work inside the radio. I dont know of any pictures. Since rig was so roughly treated you do need to open up and do a visual inspection and especially make sure that all three tubes remain seated in their sockets. Here is what I would do:
>
> 1. Unplug the rig and let it set for 1/2 hour or so that the bleeder resistors on the HV

filter caps have chance to discharge them.
>
> 2. Remove the top and button covers of the radio and be careful to unplug the yellow cable from the speaker.
>
> 3. You should see the 12BY7A tube on the RF board. Make sure it is seated in its socket. It should have a black metal shield can on it.
>
> 4. Remove the PA cage cover (top right rear). You will see the two 6146 final tubes and between them the RF Plate Choke.
>
> 5. The top of this plate choke is where you need to place a short to ground to ensure there is no voltage remaining in the filter caps. With rig turned on there will be 900vdc at this point and enough current behind it to kill you. Never point,touch or drop anything in the PA cage with rig energized. Some folks will use a screw driver to short from top of the plate choke to the metal shield. That is poor practice. Your radio is not a welder. You dont want to transfer any metal and leave arc and pit marks. Best way is to make a short jumper lead with good insulated test lead wire and place about a 4.7k ohm resistor in series with it. Resistor value isnt too critical just dont make it too high a value. Can get by with no resistor if you leave rig unplugged long enough. Place alligator clips on each end. Connect one clip to chassis ground and hold other end on top of plate choke. Dont just tap it but actually connect it there for a while. Now you have the HV filter caps discharged, but be aware there are other lower voltage filter caps (300 vdc) that can still have voltage on them for screen supplies etc so dont bare hand touch anything on the rectifier board or on RF board near base of Driver tube.
>
> 6. Now that you have 900 vdc B+ discharged it is safe to get a hold of each 6146 final tube and make sure they are seated in their sockets and that the anode caps are firmly seated on top of the tubes and that the parasitic suppressors from top of plate choke to anode caps are soldered well. Just give gentle tug on the leads. Sometimes the solder sublimates (dull grey looking) and the connections to the anodes are not good. While there see what kind of finals you have ie 6146B or 6146W and both tubes should be same designator.

Asunto: [TS-520_820_530_830] Re: Ts-520 TIF signal going to die, no acc

To measure TP-1 signal level make sure you have Screen Grid switch off. Mode switch in CW mode. Key the rig with Car Level Pot advanced and Drive Control peaked for maximum ALC reading on the meter.

I think you are saying at TP-1 you see approx 360 mv P-P, but it decays off like a capacitor discharging. 360mv is a good level and 3.39mhz is correct frequency. The 8.8mhz TIF signal will be mixed by Q2 and the TIF signal at the TIF terminal post on IF board will be approx 100mv P-P. If signal at TP-1 is decaying then signal at TIF post will do likewise.

What is the S-meter doing as the signal decays? Is it slowly falling down scale?

It sounds like you are losing ALC to Gate 2 of Q1. Need at least a 11 meg ohm VTVM or DMM to measure the AGL terminal post on IF board and see what the ALC control rail voltage is doing. Your meter will pull it down to around 2 volts, but should hold at that level.

You can connect a temporary +3vdc to the AGL terminal on the IF board and see if signal level at TP-1 stays at 360mv P-P.

If AGL voltage is decaying then pull your Aux Relay and clean the contacts as a first step.

The s-meter operates normally in the Fast and Slow positions of the AGC knob. It does not function in the Off position, as usual.

I traced the signal thru the IF board, and a normal signal exits the board to the AF board. I gave up at midnight as I had a 5:30 AM meeting, but I plan to continue the signal tracing later today.

Hello everyone,
Here's the problem that I'm having. My Kenwood TS-520SE has a wobble on sideband, plus when I talk on it, it drifts pretty bad. I have put new HV Caps in it. I have replaced 4 transistors in the 9 volt section of the FIX CH-AVR board X43-1100-00 and also put two new diodes in it. Ok, have had one other ham directing me on things to check. I have lifted the red wiring coming off the X43-1100-00 and the 9 volts that is supposed the be there is there. I found the drag on the 9 volt line seems to be coming from the RF Board. Has anyone had any such problem with a 520SE?

OK then if you assume that your load current is 50 ma (max rating of the Selenium)and you want to drop 140vdc to 110vdc then 30vdc/.050 = 600 ohms. Wattage rating = I squared x R = .050 x .050 x 600 = 1.5 watts. I think I would start with a 470 ohm 2 watt resistor after the new Silicon diode.

Of course you could measure the B+ current.

Maybe some one else with experience replacing a selenium can help you size your series dropping resistor.

>
> Are you saying the transformer secondary is 145vac? I am surprised if that is the case. I would have guessed ratio was close to 1:1. Need to measure secondary AC then can calculate what the dc output will be.
>
> Ordinarily when you replace a selenium with a silicon you end up placing somewhere around a 100 to 200 ohm resistor in series with the silicon diode down stream between it and the filter. This is because a good selenium normally has around 5 volts drop across it and the silicon about 0.7 drop so the dc output from the silicon will be approx 4 to 5 volts higher

being applied to your Pi-filter. If you know the Ma load current can calculate the value of the needed series resistor but usually just temporarily try values.
>
> You can just swap out for the silicon and install the new filter caps and see what happens to the B+ line. If it is only 4 or 5 volts more than shown on schematic I would not worry about it. Part of reason that you may currently have such high voltage is that seleniums do age and when they do the output voltage may go up. So with the silicon in its place the new output voltage may not be anywhere near what you are seeing now.
>
> I think I would install the diode and filter caps and measure the tube anode voltage at the socket and decide if a series resistor is needed based on what you find.
>
> I would not change the value of your Pi Filter resistor. I would measure it as likely carbon and may have drifted high. Its value is chosen for correct time constant for filtering. It is poor mans choke.

Heater is a term for the tube filaments. When you turn it on it
supplies AC voltage to the filaments and they heat the cathodes so the
tubes will have electron emission. If you had covers off you could see
the glow of the filaments or heaters inside the glass envelopes of the
three vacuum tubes (12BY7A driver tube and 6146 final tubes). The tubes
do get hot but not hot enough for you to feel much heat on the cabinet.
The cooling fan on rear of rig pulls air thru the PA (power amplifier)
metal gage to help cool the final tubes.

Pulled the covers off and checked everything out like you said, still
only ten ma's. Turned the heater on, this time with the finals exposed.
I only saw two small glowing spots as I looked down on the finals. How
much glow should there be?

> 3. You should see the 12BY7A tube on the RF board. Make sure it is
seated in its socket. It should have a black metal shield can on it.

Did this earlier but checked again. It was fine.
>

> 6. Now that you have 900 vdc B+ discharged it is safe to get a hold of
each 6146 final tube and make sure they are seated in their sockets and

parasitic suppressors from top of plate choke to anode caps are soldered
well. Just give gentle tug on the leads. Sometimes the solder sublimates
(dull grey looking) and the connections to the anodes are not good.
While there see what kind of finals you have ie 6146B or 6146W and both
tubes should be same designator.

Did all this, all seemed to be okay. The finals are "B's"
>
> 7.Note the filter caps standing by the Power Transformer. Are they
tall black original ones?
Yes, they look like the originals.
>
> 8. Flip rig over and look at filter caps rupture vents to see if there
is any swelling or leakage. May see convex curvature of the rubber vent
and/or white powdery deposits around the vents. If really bad may see
some brown/black tar like leakage. If caps have been changed out they
will be short black or blue units.
If the vents are the the underside of where the filter caps are

inserted, they look fine.
>
> 9. As to 10 ma resting plate current what test equipment do you have?
Unfortunately, just a cheap digital meter.

Terry,
I do thank you for responding. The receive on this radio is fantastic.
20 meters was incredible yesterday. Was pulling in Scotland, England,
Croatia like they were next door and was hearing the people they were
talking to from the states.

Of course being only a Tech, 10 meters is all I got and unfortunately 10
has been dead. I really hope I can get this rig up and running so when
it gets hot again, I'll be ready.

Thanks again for the help,
Eric

As anyone responded to help you? If so, stick with them and let me know as I am overloaded at present time.

What makes you think the heavy load is on the RF board?

Are you certain you have repaired the AVR board and it now capable of regulating? Always best to test the repairs you made and then land the radio loads. Normal load in RX mode is approx 60ma.

When I repair these boards I leave the two leads off the 9VDC wire wrap post and place a 150 ohm dummy load from post to chassis ground. If you can measure 9vdc across this dummy load then you know the repairs you made have been effective in restoring the regulator. I have a 250 ohm rheostat and vary it and monitor to see if the regulator is working after installation of any new components. If it is then I can land the load wires and if it doesnt regulate then you know you have a fault current beyond what the regulator can supply.

With the two leads lifted I would measure the resistance of each to ground. One lead will read approx 150 ohms and the other approx 2.2k ohm.

Have you lifted the wire off the 9vdc post on RF board as you monitored 9vdc output at the AVR board and observed the 7.99 vdc go back to 9vdc? Also need to lift RLR lead on RF board and watch the voltage. It also supplies 9vdc in RX mode.

Give us a little more detail why you believe AVR board is fixed and why you believe problem is on the RF board.

If your regulated 9vdc is not regulating then you will have VFO drift and FM-ing and ????

I'll be back home in Illinois in about a week (traveling to see grand-wiggles in TX) and will likely dive into the 520SE that needs a new power board. Thanks to Bob I've got a nice one to replace the dead unit.

Wire wrap is the name of the game inside this chassis, but I'm having one HECK of a time finding a simple hand wire wrap tool to fit these posts. The ones I find are for the smaller sort, not the old-style ones Kenwood used.

First thing, is it best to keep it all wire wrap in the first place?

Or should I consider soldering the new board in? Or something else I don't even know of yet?

And if wire wrap is the proper method (as I suspect it is - always worked well for me before) where in the Sam Hill do I get one of those (used to be five buck) wrap tools, not one of the hundred-dollar power wrap guns? Mouser nor DigiKey had them, and I haven't been finding any the right size in any local or on-line places that I usually use.

So, there's a few items to ponder, but nothing that needs a VTVM. Answers for this should be cake for this bunch.

Today I traced the other red wire from the AVR board to the x54-0001-00, when I lifted the first red wire from the board-just fixing to work on checks again. The reports that I have gotten when I transmit are that it sounds like the rig is starving for voltage. No one other than you has answered me.
Thanks,
Ron

Wes,

  I got my wrap/unwrap tool from JONARD Industries. It kind of looks like a fountain pen. It has an end for wrapping and another
for unwrapping. They come in various sizes....post diameter/wire diameter(gauge) to fill various needs. Not real cheap...but I found
well worth the price...sorry but can't remember price...$70 comes to mind...yea...ouch! If interested...look for "hand wrap/un-wrap tool"
on their web site. Lots to choose from.

You may want to skip the wrap tool...as when you try and get all those wraps off the posts...you're going to break more that one,
and end up with a short wire...try and re-do it IF your lucky enough to have a long enough end...and it'll break when you try and
re-wrap it. These tool like nice smooth wires...no some kinked up ones...remember those wires have been wrapped on those posts
for 30+ years!

  Make sure that you have some spare wire around...and some heat shrink tubing...as you will come up short on some of those wires
that got broken...and there's not a lot of slack to be had on some of those wires!

  Just my recommendation....

Hi Joe:

You are correct can seldom ever remove without breaking and if you did you need to cut off the old coiled end and prepare a new straight end for re-wrapping.

The Jonard is model WDUD-2224 for 22 to 24 gauge wire of the Hybrids.

Newark Electronics carries this model for $100.00 (ouch).

I never re-wrap. This was assembly line method used with wire wrap guns. Telephone companies also employed it.

If you are replacing a board easy to remove all the old wire wrap and lightly sand the posts and blow out and vacuum off all the conductive fines and then just solder the new leads back on the post. Of course have to get to clean new wire because if you try to use an unwrapped end very easy to break it.

Did a real quick Google and found that Amazon.com carries a cheaper model by OK industries. Allied Electronics has the good Jonard at $85.00 and TESSCO carries both Jonard and OK industries brand. So a more exhaustive internet search might find the Jonard even cheaper.

Ebay has a replacement 22/24 bit for the Jonard listed for $3.95 so maybe could fab a handle for it? A small tap wrench T-handle would probably work just fine.

Eric:

The glow of the filaments of the finals wont be brite. These tubes filaments are in series so if one tube had open filament neither would have any glow. So any glow is usually good unless your filament voltage was low for some reason but very unlikely. Driver tube filament has nothing to do with final tube resting plate current. I was just explaining what they meant by the Heater switch.

Did not go in to directly heated and indirectly heated cathodes. Something you can read about in ARRL handbook. By the way you can buy a watered down ARRL handbook off Ebay called Understanding Amateur Radio by ARRL. There was a lot of controversy when ARRL produced this book many years ago as old timers thought it was the beginning of the end of the old hobby. I bought it back then and still have it and nothing wrong with starting with it to learn the fundamentals including how vacuum tubes work. Dont have to build the projects in it just read the theory.

A DMM will be fine for measuring your finals screen grid voltage and control grid operating bias voltage, but I am nervous about directing you to make these measurements.

To have ability to adjust your bias voltage pot to set the resting plate current to 60ma you need:
1. Two good tubes. Good means no open filaments and good emission.
2. Operating DC bias voltage of approx -60vdc on the control grid when you flip to send.
3. Screen grid voltage of approx + 220vdc on the screen grids when you flip to send. (SG switch on)
4. Good cathode meter shunt resistors (approx 5 ohms)
5. Anode voltage of approx +900vdc at the plate caps of the finals

First check the indicated plate voltage using your panel meter HV position. Turn on rig, set panel meter selector switch to HV, flip to Send. Meter should indicate close to 900vdc. If it measures 450vdc you have lost one of the HV filter caps.

If you decide to measure control grid bias voltage and screen grid voltage we can talk some more. Is there a near by experienced Ham who could help you?

Well. Seventy dollars for a tool that is actually worth at most worth maybe TEN.

I cannot find my old "deluxe" model one, lost some time in the last couple of decades of not needing it, I guess. I think I paid about NINE for it. With the insanity of prices going goofy, make that -maybe- twenty today.

Twenty, I could do. But SEVENTY?? Plus about $12 shipping, which is another rip-off there, so it looks like altogether WAY too close to a C-note!!

If I had THAT kind of cash laying about I'd box the whole thing up and give it to one of the hybrid repair shops which are (rightfully) so well-thought-of here. (Wish I could; someone with that much experience with these beasties will obviously do a MUCH better job of the whole thing than I will, try I ever so hard. Just having all the right gear will make the difference, even if there wasn't an experience curve.)

That rather firmly settles that! Looks like I'll be soldering those wires to the wire-wrap terminals, doesn't it?

Particularly with the business about the wires being both short and somewhat fragile, solder it shall be, then.

Terry:

First off, I really want to thank you for all the help and patience that you have exhibited so far and for not talking down to me and my limited abilites and knowledge. I'm also thankful that you have enough confidence in me not to do something ignorant or put myself in harms way. I know some in the group do not have this type of mindset. So once again, thanks for everything.

I will check the indicated plate voltage using the panel meter when I get home and let you know the results. I am also trying to find a local ham with the abilities to work on this radio when I feel uncomfortable with the process.

Thanks again for making this a enjoyable, educational endevour.

Eric,

Very good advice from Terry!

If I may add an additional reference book to Terry's reference book suggestions and that is John T. Frye's "BASIC RADIO COURSE". This book unfortunately is out of print. However you may find it at your local public library along with the ARRL publications Terry spoke of, at your local public library and possibly at some used bookstores. I found my hard cover copy of the BASIC RADIO COURSE, 1961 edition, at a used book store for $2.

Amazon.com currently shows they have a few hard copy editions ofthe BASIC RADIO COURSE available on their website with prices between $22 and $25.

There is an eBay seller who is currently John T.Frye'sBASIC RADIO COURSE 1951 edition on CD for $8.99, see eBay ad #200692897318. I bought the CD so I could compare it with my 1961 edition. It contains everything my 1961 edition has except for the chapters on transistors.

This book has an excellent chapter on how a basic receiver works, a subject that all hams who service their own ham gear should fully understand.

The book discusses vacuum tube theory including the "BEAM POWER PENTODE". For those who don't know what a Beam Power Pentode tube is or even looks like, have a look inside the final amplifier of your hybrid, the 2 "6146" final tubesare "Beam Power Pentodes".

A Beam Power Pentode has the same number of elements a normal Pentode tube has(5 elements) except that the beamforming screen grid #2 is different and operates differently than in a typical Pentode tube.

A typical Pentode tube screen grid #2 is a wire mesh and electrons flow "through" the mesh. However, a Beam Power Pentode screen grid #2 is designed differenty, they are arranged in such as manner that electrons flow "Past", not "through", screen grid #2. As the electrons flow "past" the beam forming elements they are "pushed" into a tight beam that is focused at the tube's Anode. The BASIC RADIO COURSE discusses this and includes a drawing of how all this works.

I highly recommend this book for those who wish to learn electronic theory.

I recommend purchasing the earlier editions of the ARRL handbook, 1970 and earlier.I find the earlier editions are easier to read and understand.

Eric/Mike:

We never known for sure what anyones knowledge or experience level is. All we can do is gauge it by how and what they say in their post. I would much rather assume minimal knowledge than otherwise. Never intend to hurt anyones feelings, but feelings can be easily fixed and some injuries and death are a little more permanent.

Mike is correct Fryes book was one of my first and still on my book shelf. He had a unique ability to write for the technician level and as Mike notes the mid 70s ARRL handbook (bible) is better 1st handbook for anyone who owns tube rigs.

Understanding Amateur Radio condenses the entire Handbook fundamentals into under 100 pages, Fryes primer covers it in approx 200 pages while the Handbook devotes chapters to Dc/Ac theory, components,power supplies,oscillators, amplifiers, tubes, transistors,transmitters, receivers and so on.

42587. Looking to clean my 820 - digital display keeps shifting (but not going out)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

Topic: 42587 Message: 42587

My Great Uncle has been put in a nursing home but sold me his TS-820 with the VFO, MC-50 mic and speaker, and I take my Tech exam a week from Saturday. I'm excited to get the license so I can start talking, but in the meantime I've been playing around listening to the TS-820.

He also sold me a Yaesu FT-757GX with its power supply and FT-757AT automatic antenna tuner, so I'm going back and forth listening to each of them.

I'm really liking the Kenwood, though. I'm tempted to sell the Yaesu and keep the 820! I know very little about them, though - I've never been a ham but have always been interested.

How hard is it to clean contacts on the 820 without getting shocked to high heaven? One of the main things I want to do is get the digital display to quit hopping around like it does. It changes numbers often rapidly, but thankfully it doesn't just completely go off. It's just fairly erratic in changing frequency numbers.

Any help you can give me would be so greatly appreciated! I'm sorry I'm not as up to speed as everybody here, but I'm trying to learn quickly so I can contribute to the group. I am not a complete tech newbie - I do the IT at our church and am very technically oriented, but I've never worked with ham radios.

Thanks to everybody.

Barry

Hello group,
Since the topic has come up I have decided to show an experiment I have been working on for several months. It is not complete and not proved out so I do not recommend tearing into your rigs just yet. I am not a fan of wire wrapped terminals. Never was. I do not care to solder to the post. No matter how well I clean them some just will not solder. Besides It does not look very professional. So I have been in search of an efficient and safe connector option. I have finally settled on the sub miniature molex pins. I have set the male posts into the 530's PCB's and solder the female connector onto the wire. Notice I have not done this to the 800V connection yet. I am not sure of the size I want to use. It may not work out so easily and I have not tried any prototypes yet. The PCB holes need to be drilled out to fit the pins and it works fine with the small sizes but may not work with the larger size needed for the 2 wires on the 800V connection. Please take a look at it and give me your comments. Mike and Terry, I am hoping you look at this and let me know if you see any problems here. Maybe something I have missed or not considered. This 530 is my full filtered CW rig and I have been using it with the new connections for about 2 months. So far it has performed well. I have put a lot of work into this rig in the last year to bring it back to life so if you see something you do not like or concerns either of you please tell me. I am a hobbiest not an EE. I build most of my own stuff so I am not a stranger to criticism. I can take it. I have nobody down this way to work with. All appliance ops. HiHi

Barry
Your going to love that TS-820S Radio. Here is a site that will
give you some guidance to repair the VFO problem. I have an TS-820S
with the same problem.
http://www.n6wk.com/kenwood/TS-820-VFO--servicing.pdf My advice
keep the spare radio.

Barry,

"How hard is it to clean contacts on the 820 without getting shocked to high heaven?"

Don't clean contacts with the power on. There is no reason to ever clean anything on your rig with power applied. Have the rig unplugged from the power and let the caps discharge completely before touching it. You can clean N.O. relay contacts by manually closing the relay with your finger.

73,

Bill

I'll cast my vote to the "don't re-wrap" crowd. I used to work for Western Electric years ago. They pretty much invented the process, and the rule was if you had to re-wrap a post, you should always solder the repair job.

Wire wrapping is a "gas tight" process. The wire bites into the corners of the posts, and once the post and the wire have done that the first time, that gas tight process can never be accomplished 100% effectively again. W/E always recommended soldering if reworking a connection.

Just my recollection.

Barry & all,

I hope this finds you well. Good luck on your test. Keep the next step on your horizon and set your next goal for the General. It will really open up your options in using these 2 radios. I might suggest you follow the thread on this reflector between Terry, MIke, and Eric WD8OWB. Its heading is TS-820 low plate current. The advice Mike & Terry have given to Eric also fits your situation. Build a good foundation of knowledge and Ham radio will give you a lifetime of fun and satisfaction. If money is not an issue I would suggest holding on to the Yaesu gear. There are situations where having a no-tune solid state rig will come in handy and having rigs dedicated to different bands/antennas can also help make operating easier. The other factor is once sold it will be tough to replace it if you miss it. At least keep it until you have a knowledge base that lets you make an informed choice.

Good Luck to you again & Vy73,
Mike K8SYN

You are exactly correct how the wire wrap works. I too worked many many moons ago for Western Electric, but did not like the travel away from home.

I always re-solder. Problem is that the exposed end of the post has oxidized over all these years and unless cleaned to almost brite metal can not get the solder to wet very well. So I file clean and hate to do that as you are dropping the conductive fines on the PC board. I have an adapter for my shop vac and my wife helps by vacuuming as I file clean the post. Hate this as never 100% sure have all of this conductive powder removed. So far no problems, but always makes me nervous. Once you have clean metal very easy to make a wrap or two and the solder flows well.

I checked the indicated plate voltage using the panel meter HV position and read 900vdc.

> The glow of the filaments of the finals wont be brite. These tubes filaments are in series so if one tube had open filament neither would have any glow. So any glow is usually good unless your filament voltage was low for some reason but very unlikely. Driver tube filament has nothing to do with final tube resting plate current. I was just explaining what they meant by the Heater switch.
>
> Did not go in to directly heated and indirectly heated cathodes. Something you can read about in ARRL handbook. By the way you can buy a watered down ARRL handbook off Ebay called Understanding Amateur Radio by ARRL. There was a lot of controversy when ARRL produced this book many years ago as old timers thought it was the beginning of the end of the old hobby. I bought it back then and still have it and nothing wrong with starting with it to learn the fundamentals including how vacuum tubes work. Dont have to build the projects in it just read the theory.

Don:

If the Molex connector you are using is a factory matched set see no reason why wont work. I think I would like to measure the resistance across the male/female contact interface. I would think it should be as good or better than a relay contact. Most relays contact specs are a maximum of 100 milliohms with 50 milliohms considered a good contact.

As most hams dont have expensive milliohm meters I would use the standard 6V 1A relay contact test. Apply 6volts dc at 1 ampere across the molex male/female interface and use your DMM to measure the millivolt drop across this contact. With 1A load current flowing whatever MV reading you get will be the Milliohms resistance of the contact ie if you read 50.0mv then the interface resistance is 50.0 milliohms.

Would sure make it easy to change boards and to troubleshoot. Lot of work to remove boards and drill out and mount all the new male post, but when complete should be a nice mod.

Only other question I have is how will the lead wire be connected to the female pin? Will it be a crimp? Have to make sure dont introduce high resistance here. Wait a minute I think you said will be soldered on?

I forgot Gordon had these good close up pictures.

I use a artist brush and apply tri-flow to the bearing. Sometimes you will find some one else has been there before you and applied grease. A little lithium grease doesnt hurt, but dont want any hardened grease on the ball and race. Make sure you exercise VFO several times through complete rotation when you apply the DeOxit to the rotor shaft wiper. Also blow out with canned air.

Whatever you do DO NOT lubricate this wiper. The whole idea is that you want the RF current to flow from rotor to capacitor frame thru a very low resistance contact. Lubrication defeats the purpose. The wiper is made of phosphor bronze which is very high conductivity and self lubricating. Also, NEVER reach in and attempt to bend with a screwdriver or any other tool. Phosphor bronze has spring temper and designed to apply correct pressure to the machined surface on the end of the rotor shaft. Over time it just oxidizes and get blackened and green unless someone else who doesnt understand how it works may have lubed it before you. So good cleaning with DeOxit should remove any grease and oil and any oxidation.

Since you went to all this trouble spray several times and give several full rotation cycles.

Terry,
I will set up and do the mOhms test. Have to work up a 6V 1A supply. Have to see what I have and will let you know. I did voltage checks after the mod and did not see a difference. All worked same as before. I had thought about the contact points but did not think to run this test and the voltage checks in rx and tx were good. But that is why I put this post out. Good info. Thanks. By the way, the pins are matched sets.
Also, I took the Rigol plunge so keep looking for your commission.

OK Don just a suggestion. If a factory matched set probably just fine.

I suppose weekly you could plug and unplug to wipe the contact area! I suspect no difference than any of the other Molex connector rigs until about 30 years from now. As you know they are not without there problems.

Let me know what you think about the Rigol when you get it.

Will keep eye out for the check!

I have a dumb question. I am trying to hook up a Ameritron 811a amp the the ts 820s and I used pin 4 for the common ground and pin 5 for the relay and pin 6 for the alc on the remote connector. According to the diagram between pin 4 and pin 5 should be a n/o contact for the keying the amp or am I doing something wrong? The amp will not key.
Robert.

There are pins available for use with 25mil square posts. But they are designed to be crimped to the wire. You do not want to crimp to a wire wrap wire. You need to solder them.

I have a batch of these pins but I don't have the part number.

> Hello group,
> Since the topic has come up I have decided to show an experiment I have been working on for several months. It is not complete and not proved out so I do not recommend tearing into your rigs just yet. I am not a fan of wire wrapped terminals. Never was. I do not care to solder to the post. No matter how well I clean them some just will not solder. Besides It does not look very professional. So I have been in search of an efficient and safe connector option. I have finally settled on the sub miniature molex pins. I have set the male posts into the 530's PCB's and solder the female connector onto the wire. Notice I have not done this to the 800V connection yet. I am not sure of the size I want to use. It may not work out so easily and I have not tried any prototypes yet. The PCB holes need to be drilled out to fit the pins and it works fine with the small sizes but may not work with the larger size needed for the 2 wires on the 800V connection. Please take a look at it and give me your comments. Mike and Terry, I am hoping you look at this and let me know if you see any problems here. Maybe something I have missed or not considered. This 530 is my full filtered CW rig and I have been using it with the new connections for about 2 months. So far it has performed well. I have put a lot of work into this rig in the last year to bring it back to life so if you see something you do not like or concerns either of you please tell me. I am a hobbiest not an EE. I build most of my own stuff so I am not a stranger to criticism. I can take it. I have nobody down this way to work with. All appliance ops. HiHi

Robert,

Did you forget to flip the amplifier's XMT/STBY switch to XMT? If the wiring is right between the AL-811 and the transceiver's rear accessory socket but the XMT/STBY switch on the amp is in "STBY" then the amp won't key. This is a switch that quite often is not set to XMT which prevents the amp from being keyed. When the wiring between the 820 and the amp's RELAY socket is right AND the XMT/STBY switch is set to XMT, the amp will key and the RED led above the XMT/STBY switch should light.

If you suspect the relay is not working in the amp, simply short the RELAY socket's center connector to the amp's chassis with NO Rf drive applied to the amp and the XMT/STBY switch set to XMT, the relay should energize in the amp.

I use simple stereo interconnecting cables cut to the length I need, leaving one end with an RCA male plug that fits the AL-811 RELAY socket. The center conductor of the stereo cable connects to pon 5 and the shield to pin 4 on the 820's 8 pin socket. ALC is connected using same stereo cables cut to length, center wire is connected to pin 6 and shield to pin 1 or 4 on the 820's accessory octal socket. The amplifier voltage and current is "12VDC at 100ma" so stereo cables can easily handle the voltage and current. I have the AL-811 3 tube amp.

A quick source of 6VDC is a 6VDC lantern battery. You can get them at
Walmart.

Thanks for all the help Hybrid Users team!
Got back from vacation and installed an INRAD #98 in place of the used TRIO CW filter.
The radio tunes normally. CAR control is around 4 to get full drive instead of around 8.
Just like it is was when I had no CW filter.

So, the problem was the actual filter itself.

The final measurement came down to looking at the amplitude of the waveform on the oscilloscope before and after the filter and comparing it to Terry's expected loss.

One more success story for the group!
Thanks, Stephen

> > >
> > > All of us had to start building test bench slowly over time. I and Mike and others have posted many times on what is needed at a minimum to troubleshoot and maintain a Kenwood Hybrid and in what order to buy each piece. You dont need a lab grade RF bench, but something on order of Heathkit level is needed at a minimum. Sometimes there are alternate methods to accomplish the steps and other times you have to bite the bullet and realize the easiest and best method is to use the service manual prescribed test gear. There is no "only one way" but very often one way is clearly superior to others.
> > >
> > > Filters can be swept manually and the response shapes plotted on graph paper. I bit tedious but was done that way for years. I have notebook full of graphs before I got a decent sweep generator. Now I am lusting for VNA and/or Spectrum Analyzer and Tracking Generator. Even the old manual method requires a rf signal generator and a means to detect

the RF output voltage at the frequency steps you inject.
> > >
> > > I dont know any way to measure the filter insertion loss without a means to measure the RF voltage at the input and at the output of the filter. Can use the rigs internal Carrier Osc signal, but still need a RF millivolt meter or an O-scope. No way around it.
> > >
> > > If you want to test the filter on the bench you can do that but you should terminate the input and output. I wont go into that test procedure here. Once you get correct gear I highly recommend you sweep any used filter on the bench before installing in rig.

Topic: 42556 Message: 42608

Ok as I mentioned this tells you that your HV power supply is working, but not that you have 900vdc on each tube anode. We will safe that for last.

With the rig off you can safely measure the cathode resistors. As I mentioned if they were blown open you would have no plate current at all. With 10 ma resting plate current they cannot be open, but typically they do drift high with age. Measure from Pin 1 of 6146 tube socket on Final board to chassis ground.

Really need to measure operating bias and screen grid voltages. If you are comfortable I would place jumper lead on your negative or black test prod of your DMM and connect it to chassis ground. This gives you only one test prod to handle and control. Now you can touch the positive or red prod to the 6146 tube socket pins to make the voltage checks. You will take two sets of readings. One in receive mode and one with the rig flipped to Send. Again make sure Screen Grid switch is turned on.

You will measure operating bias at the final board 6146 tube socket Pin 5. In receive you will have approx -100vdc and with rig flipped to Send you will have approx -60vdc. You will measure screen grid voltage at Pin 3. In receive you will have approx +260vdc and with rig flipped to Send you will have approx +220vdc.

Make sure your test leads for your DMM are in good shape with no cracked insulation and no conductors exposed at the bananna plug ends at the meter or at the probe/prod ends.

Terry K9TW

So any glow is usually good unless your filament voltage was low for some reason but very unlikely. Driver tube filament has nothing to do with final tube resting plate current. I was just explaining what they meant by the Heater switch.
> >
> > Did not go in to directly heated and indirectly heated cathodes. Something you can read about in ARRL handbook. By the way you can buy a watered down ARRL handbook off Ebay called Understanding Amateur Radio by ARRL. There was a lot of controversy when ARRL produced this book many years ago as old timers thought it was the beginning of the end of the old hobby. I bought it back then and still have it and nothing wrong with starting with it to learn

the fundamentals including how vacuum tubes work. Dont have to build the projects in it just read the theory.

> > > >
> > > > All of us had to start building test bench slowly over time. I and Mike and others have posted many times on what is needed at a minimum to troubleshoot and maintain a Kenwood Hybrid and in what order to buy each piece. You dont need a lab grade RF bench, but

something on order of Heathkit level is needed at a minimum. Sometimes there are alternate methods to accomplish the steps and other times you have to bite the bullet and realize the easiest and best method is to use the service manual prescribed test gear. There is no "only one way" but very often one way is clearly superior to others.
> > > >
> > > > Filters can be swept manually and the response shapes plotted on graph paper. I bit tedious but was done that way for years. I have notebook full of graphs before I got a decent sweep generator. Now I am lusting for VNA and/or Spectrum Analyzer and Tracking Generator. Even the old manual method requires a rf signal generator and a means to detect the RF output voltage at the frequency steps you inject.
> > > >

Brad the problem is once you unwrap (people are doing this by just grabbing end of the lead wire and untwisting it off the post) you end up with a brittle coiled end that commonly breaks off and you cannot re-wrap of course without the proper tool and almost always have to cut back to sufficient length of fresh conductor and the lead wire may now be too short. Also, some post have two wraps on them. The density on some boards like the IF board means you have very close quarters to work with and not easy to get a tool in there.

Troubleshooting would be so much easier if you could simply unplug and plug the lead from the terminal post.

Yes it will work. It does not have to be 6vdc. You could use a 12vdc or 13.8vdc rig power supply. Relay engineers standardized on 6vdc and 1amp as the power level that provides enough heating to puncture the film that develops on relay contacts.

Here is a simple low cost milliohm adapter for your DMM that uses a LM317 to provide constant current source.

How would you use it? Well anytime you suspect bad RL-1 Aux relay or RL-1 Antenna relay contacts you can measure the before and after resistance and the effectiveness of cleaning of the contacts.

This probably doesnt need to be said, but you just dont just place 6vdc or 12vdc power source across low ohm resistance you want to measure. You will have a whole lot more than 1 amp for a short period of time!

I have a bench supply that has adjustable voltage and current output. If you use a 6vdc battery you will need series resistor of 6 ohms to limit current to 1 amp. P= 6 vdc x 1 amp = 6 watts so a 10 watt resistor would be a good value.

6 ohm resistors are commonly available for LED lights for auto application. Check Ebay or just make your own by paralleling resistors.

Sorry if telling you the obvious.

A standard carbon-zinc 6 volt lantern battery is rated at approx 7AH so it would supply 1 amp for about 7 hours. I think you can go to Dollar Store and buy a plastic holder for four 1.5vdc "D" cells. Probably cheaper than buying a Lantern battery. OK enough on this subject!

Certainly not directed to you Mike. I know you fully understand. Just never know how far you have to take any of this stuff anymore. I guess better to give more detail than to assume anything?

Would probably be "Good Enough" to just measure contact resistance with DMM, but like all things in electronics there is a wide definition of good enough and then there are "Standard and Good Engineering Practices". Test equipment and measuring have always interested me. Problem is good test gear is so expensive. This is why I am interested in watching the development of USB based test gear for the lap top. Prices are coming down on things like RF Power millivolt meters and VNAs.

I think if I had a kid in EE school I would coach him/her to major in Measurement & Control Instrumentation and not RF or Telecommunications. I think more job opportunities.

Take Care
Terry

Sorry for the delayed response. At work. I did not want to use battery but I could not get my variable supply down past 9V. It was getting late, got to get up at 4AM, so I went to bed. I will get back to it on the weekend. May have to repair or replace my variable supply. I did check the resistance across the connection. I just put male a nd female together and measured .2 ohms on a fluke 27 but did not continue any further. ran out of time. I appreciate the responses and do not mind extended instructions. Will let you know what I find.
Thanks guys, Don K5HFG

Thanks so much to everybody for the incredibly helpful advice and for being so considerate. I'd never work on anything plugged in, for sure - I wanted to make sure that it was safe to open it up while unplugged and work on whatever I need to work on without doing something that I'd regret. I mainly wanted to know what wouldn't bite me when working on it.

I'll read some of the other posts that were recommended, and I printed the PDF file of the VFO work. I was hoping to work on it last night but church went a little late and I got busy afterwards, so it'll be better to work on it Saturday when I can take more time anyway.

I notice the knob controls are a little scratchy when I rotate them as well. What is the process to cleaning them out? Is it very hard to do?

I bought some good contact cleaner last night and also have a full can of compressed air that I'll use.

Barry

Barry:

One more thing I would do with the VFO out is to lubricate the entire gear train. This means all the brass gears including anti-backlash, pinions, and the shaft bushings.

I recommend using Tri-Flow with an artist brush. I spray a little in a solo cup or old pill bottle and then dip the brush tip in and apply a very lite coat of Tri-Flow and then run VFO knob stop to stop couple of times to distribute the lube.

Your VFO will run silky smooth.

I'll do that, Terry. I think I can get some Tri-Flow at Grainger nearby.

How hard is it and what is the process to take the knobs off and to clean the switches since they're scratchy sounding when I move them around?

Barry,

Most of my work has been on Drakes and not Kenwoods. Most of the Drake guys will only use the DeoxIT line of contact cleaners. Some of the contact cleaners will cause the phenolic material of the wafer switches to swell. If that happens you have turned your restoration project into a "parts" rig.

DeoxIT is made by Caig Labs. I have found it online directly from Caig, on ebay, and on Amazon.

Another DeoxIT product is FaderLube which works wonders for pots and shaft bushings.

73,

Bill

I use only DeoXit D5 for switches and relay contacts and DeoXit F5 for pots. I have been using these products for years and never had a problem.

When using DeoXit and canned air from Walmart, always follow the safety precautions printed on the cans! Some contact cleaners are flammable and it only takes a small spark to ignite the cleaner. Use only enough cleaner to accomplish the job. Never use excess amounts of cleaner and always ensure all the cleaner residue is removed with what ever source of force air you use. This is especially important in areas where the cleaner can form a "pool" around components. I found this out when cleaning a variable capacitor in a Heathkit SB-303 LMO. I "thought" I removed all the cleaner residue. The symptoms were the LMO drifted excessively. Only when I was able to remove all the cleaner residue that had pooled in the LMO did the LMO settle down and not drift. Never assume you got rid of all the cleaner. If necessary, perform a thorough visual inspection to ensure the cleaner residue is gone.

Canned air from Walmart or other sources for canned air, will, if not used properly, result in the propellent being sprayed onto the component and/or your hands/fingers. Always keep the canned air can upright, never sideways or upside down when using! The propellent is very cold and can cause burns to your hands/fingers if you do not follow the instructions on the can!!! It's normal for the canned air can to feel cold during use.

From: Terry Wagoner
Topic: 42587 Message: 42623

It is not easy to get contact cleaner in all the pots and switches. I think the TS520 is about the easiest. When you look at a pot it has 3 terminal leads that come out of it. Some are two pots on concentric shaft. Ideally need to shoot the contact cleaner into that access window where the leads enter and run pot thru its range and then blow out with canned air. I like to apply Deoxit Fader Lube after that as it is made for carbon trace pots.

I have tried using the hard extension nozzle and different flexible nozzles without 100% success on all pots and switches. Push buttons and slide switches also present a challenge.

Maybe some other have better success at cleaning the pots and controls than I do. I did not respond originally hoping that they would answer you and I could learn from them.

I tell customers I lube and clean those controls that are accessible. Some folks dont even know there are DIN switches on aux sockets on rear panel.

I think some people believe they are getting cleaner in when really not getting very much to be very effective. Some talk about sitting rig on back panel and running cleaner on the shafts and hope it gets past the shaft grease and leaches into the pot body. I dont think that works.

You will tell if you got it in the pot window and did any good if you exercise it and the scratchy sound is eliminated. AF and RF gain usually worse offenders for scratchy sound in speaker.

Lack of regular use and exercising of the controls will very quickly result in noise returning.

Robert, you said, "Best source of such slugs are old CB radios,".
Is there a particular brand of CB radios, model, manufacturer that is a likely donor? (just in case my 830S needs a slug or two)
Thanks,

I think now some of what you are looking at may be due to the difference in line voltage from then to now. I would probably leave it alone. If you have 200wvdc caps 128vdc wont hurt them. I would monitor 820 ohm series resistor to make sure not getting too hot. Of course pretty easy to increase series resistor and dial it in to voltage noted on the original schematic. Terry K9TW

Barry:

I am not trying to discourage you. Just trying to be honest. The real truth is the best fix is to replace noisy rotary pots and switches and slide switches with new ones. Unfortunately not possible and a lot of work.

Years ago I unsoldered pots off PC boards and unfolded the metal tabs on the pot body and used pencil eraser and cleaned the carbon ring and cleaned the spring metal contact and maybe applied "blue stuff" TV rotary tuner contact cleaner (very popular and effective cleaner). I soon realized this was silliness when should have just installed a new pot.

Look at all the hybrid restorers websites and read carefully their refurb/repair procedures and you will see "weasel words" like clean all accessible controls or clean as necessary. Call and discuss this aspect of refurb with them on phone. Reputable ones should tell you what they really do.

I have had several of these radios appear on my bench 2 to 3 years after complete refurb and not unusual for them to have a noisy AF gain pot.

Some folks report success with use of Corrosion X or WD-40. I have never used either one. In my opinion most of us are doing more spraying at than spraying in these controls.

I discussed this one time with Ken K4EAA and he admitted not an easy task and no magic cleaner or method short of removal and dissassembly of the pot or switch. Not many are going to do that and if you did, sure would want to investigate availability of a new or NOS control.

I really would love to meet someone who tells me they can effectively clean and lube ALL the pots and switches in a hybrid. I want to apprentice under that person. If they are doing it need to share with us. Should not be a trade secret.

No, nothing in particular. I have not done a comprehensive survey. I would try and stick to a quality brand name such as Hygain, Pace, Midland. I do think the Hygain coils look similar but it's pretty much a catch as catch can, cut and try situation.

Don't ignore old AM/FM radios of similar vintage, either.

Good Luck!

OK no shame in that.

As teacher you have to know that Telling is not the best medium. Telling and Showing much more powerful assuming the one showing isnt teaching bad practices. Pretty hard for a trainee to recognize that. Just have to place trust. Sometimes it is easy to tell a cowboy.

Would appreciate you letting us all know what you find.

I hope you came to this conclusion based on your confidence to safely measure final tube operating bias and screen grid voltage and not to spray contact cleaner on pots and switches.

With 10 ma resting plate current they cannot be open, but typically they do drift high with age. Measure from Pin 1 of 6146 tube socket on Final board to chassis ground.
> >
> > Really need to measure operating bias and screen grid voltages. If you are comfortable I would place jumper lead on your negative or black test prod of your DMM and connect it to chassis ground. This gives you only one test prod to handle and control. Now you can touch the positive or red prod to the 6146 tube socket pins to make the voltage checks. You will take two sets of readings. One in receive mode and one with the rig flipped to Send. Again make sure Screen Grid switch is turned on.
> >
> > You will measure operating bias at the final board 6146 tube socket Pin 5. In receive you will have approx -100vdc and with rig flipped to Send you will have approx -60vdc. You will measure screen grid voltage at Pin 3. In receive you will have approx +260vdc and with rig flipped to Send you will have approx +220vdc.

Terry
I think you made some comments somewhere else but when I looked for "Deoxit" it was like looking for Loctite. There are so many types, uses and numbers. I have some Deoxit D100 that I would like to use to restore the VFO wiper. Do you think that will OK, followed by a good wiping and blowing off of the remaining Deoxit?

Gregory:

Most of us use D5. If you go to Caig site you can read the formulation and recommended uses. D5 has 5% active ingredient and some naptha (solvent) in the formulation for degreasing/cleaning. D100 has 20% active ingredient and no solvent. I think the D100 is recommended where there is concern for sensitive plastics. It also states the dispenser gives short metered shots.

I am not a Caig expert. However, I dont think you would have any problem using D100 to clean the rotor shaft wiper as you note you will blow put with canned air.

People use a wide variety of favorite contact cleaners in these rigs ranging from CRC, LPS, MG Chemical, Chemtronics, Radio Shack brand, on and on and on.

I dont like any that are oily.

Just dont use any lubrication on this contact. As I mentioned in my first response to you the wiper is phosphor bronze which is self-lubricating and you are trying to get a high conductive path for the RF current from Rotor to Frame. Non-conductive grease or oil will defeat this.

Many Many years ago Cardwell sold a conductive grease for their capacitors. I have heard of people buying conductive grease (silver and carbon impregnated) and using it to lube air variable capacitors bearings. I would never put any conductive grease in any of the Hybrid air variable capacitors where it could migrate and cause a short circuit or conductive path to ground.

Good day to all & I hope you are well,

If you follow this link it will take you to the Caig products site and you can view/print a PDF with product selector information. : store.caig.com select the learning center tab and about half way down the page is a link to the product selector pdf

My personal preference is D5 as cleaner/restorer and fader lube follow-up in controls as I've seen others mention here. D100 is pretty much pure cleaner with no flushing action with a non-metered valve. It will work in your application but you may have to work more to get it in and out of the pot. I find it useful to use a piece of stiff wire or wooden toothpick to guide the cleaner into the control or contact area. I've also used 50cc insulin syringes to get cleaner into a tight spot or under a rubber switch pad. These have a very fine needle and will get into places that look sealed. Also they have no over-spray. If you un-bend a paper-clip you can use it by placing one end at the control opening and after spraying some cleaner into a small container(pill bottle cap or such) you can then trickle the fluid down the wire and into the device to be cleaned. If you use the syringe it is pretty much a one-shot as the cleaner will destroy
the rubber piston on the syringe in a couple of days. Try to always use the minimum cleaner to accomplish your task and I try to never spray directly into the device as it usually means a clean-up job after it gets on everything on the board. Probably the most important tool in your arsenal on these type repairs is patience. Better to go slowly and meticulously than to have to finish up your initial repair and then have to fix the stuff you broke fixing the first part.

As a source for Caig products I use MCM electronics. They have sales on these products a couple of times a year and have reasonable prices and quick delivery. In short; Deoxit and Tri-Flow are must haves on my bench. I would avoid having WD-40 anywhere near electronics. It will do more harm than good.

In closing I would like to take a line to remember and thank the men who stormed the beaches on D-Day. June 6th was a hard day for them but they faced it and did what had to be done. God bless them and every other soldier that walks into harms way so we can live free.

I hope this ramble gives you a little help. I just wanted to add my 2 cents to the good advice you've already been given.

Vy 73,
Mike
K8SYN

The ferrite core adjustment tool was there when I got home this weekend, so I was able to try an alignment to see if that would help my problem of no ALC on 28MHz.

I put a little drop of penetrant on the slugs first, but didn't have brush so not sure if the oil penetrated the threads as opposed to going straight through!

Anyway I went in the order of the manual. Aligning ANT and MIX coils first of 1.8 and 28.5.

Got another s-point from the 1.8 coils, and 28.8 up from S6 to S8.

But the 21MHz slugs wouldn't shift so I had to stop there. I will get a brush tomorrow and see if that helps get penetrant into right place to free them. They are not cracked.

I moved onto Drive coils. 1.8MHz could be peaked, but as I didn't have any ALC indication whatsoever I couldn't peak the 28 coil!

Moved onto some another receiver alignment operations detailed in manual. I peaked the IF board but it was pretty much peaked anyway.

Zeroed the S-meter, and checked AVR 9V which was 9.08V. I set to 9 exactly. Also set AGC voltage on the avr board which showed 3.08V so I set to 3.3V.

I found a really strange thing when going through the manual. When I tried to peak WWV frequency I couldn't, as though I could hear the calibrator signal I had no s-meter deflection on that band switch position. On 14MHz position I don't get s-meter deflection unless I peak with Drive control, but the Drive control is not operative on WWV so it may be same thing on WWV. I don't want to mess with T4, T5 and T3 on the RF board with no s-meter to guide me. Any suggestions?

So that's where I am for now, but at least I had a couple of QSOs last weekend (special stations Slovenia and Switzerland).

> Oh I also tried to improve the VFO tracking but even going backband forth many times I couldn't get it really accurate at both ends 0 and 600. It's a slight improvement on how it was tracking before, and if Inuse calibrator again at 600 end then it's spot on. Without recalibrating against marker I can get it to 5.5000 at 0 end and 4.9004 at 600 end which will do for me.

> >
> > Probably easiest is to take a look at Transmit Mixer output at the MD terminal or I believe you also have a TP-1 on the RF board. Should see something close to 2 rms volts or 6 volts P-P. If low there take a look at your Het Osc input. Het Osc serves as the LO for the Mixer and TIF as the RF input. TIF seldom problem but it could be. Output at MD is the actual transmit frequency which will be Het minus TIF. Should have about 1 volt of Het at TP-3. If low try adjusting the Het Osc coil. Make sure you peak it on slow side of the response curve and back off a little.

> > > >
> > > > 43 x 1.414 = 60.8 peak rf volts
> > > > 60.8 - 51.4 vdc bias = 9.4 volts difference. This is reason why I have FSD ALC indication. It is normal to require more Car Level voltage on 10 meters. If unsure just set it Full CW to start with.
> > > >
> > > > -51.4/1.414 = 36.0 rf volts. You must have greater than 36.0 rf volts at -51.4vdc operating bias to get any ALC indication. The Rf drive signal must make the 6146 control grid positive with respect to the cathode so that ua grid current flows to produce any ALC indication. The greater the delta between dc bias and RF drive voltage on positive swing of the RF envelope the higher the ALC deflection will be.
> > > >
> > > > So you need to load your rig on 10 meters into dummy load. Since you have no ALC indication use a workaround like peaking the Drive Control on receiver back ground noise or use the Marker. After loading to full load flip the SG switch off and make the RF drive and DC bias voltage measurements on the 6146 control grid as I did above.

I would also be very careful citing and observing any of these "service bulletins". I am very skeptical of most of these as some are just flat wrong. Putting star lock washers on circuit board to cure VFO drift isnt first thing I will ever reach for! They appear to me to be nothing more than a list of one line anecdotal entries submitted by owners and perhaps Kenwood service center bench techs? One line entries with no details, no basis, no explanations are not what I would expect from a factory authorized service bulletin.
> > > > > > >
> > > > > > > I have worked on probably 30 or so TS520s in a 10 year period. Not an exhaustive number, but enough to know that all but one left my bench with adequate ALC indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.
> > > > > > >
> > > > > > > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had

called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> > > > > > >
> > > > > > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > > > > >
> > > > > > > > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.
> > > > > > >
> > > > > > > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.

> > > > > > > >
> > > > > > > > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.

You can also get DeOxit products at most Guitar Center stores in the ProAudio section. The one here in Nashua, NH carries D5, F5 and G5.

Amazon.com carries all the Caig products, for a lot less than anywhere else, unless Caig has something on sale. (Which they do occasionally!)

Hi Adrian:

1. You dont need any ALC indication to adjust the 10 meter drive coil. Set the Drive Control to 1200 then use an RF probe/VTVM/DMM, O-scope, or RF Millivolt meter to peak the RF drive at the Plate of Driver Tube or at the Control Grids of the 6146 finals. If you have a single diode RF probe best to just monitor the RF voltage at the finals control grid. Just set Car Level pot to full CW to ensure you have good TIF level.

2. Did you set the VFO dial to zero (15.0mhz) to see the Marker signal on the S-meter to peak the WWV coils? Tune the VFO for max S-meter indication. You then peak signal with T4 and T5 for max S-meter indication and then adjust T3 for max S-meter indication and then back off T3 1/4 turn CCW. A better way is to use a RF sig generator and inject a 15 mhz signal into the SO-239 connector. I usually start with a -73dBm or 50.0 uv signal level and reduce the sig gen level as I get the tuned circuits peaked.

> I found a really strange thing when going through the manual. When I tried to peak WWV frequency I couldn't, as though I could hear the calibrator signal I had no s-meter deflection on that band switch position. On 14MHz position I don't get s-meter deflection unless I peak with Drive control, but the Drive control is not operative on WWV so it may be same thing on WWV. I don't want to mess with T4, T5 and T3 on the RF board with no s-meter to guide me. Any suggestions?

> > >
> > > Probably easiest is to take a look at Transmit Mixer output at the MD terminal or I believe you also have a TP-1 on the RF board. Should see something close to 2 rms volts or 6 volts P-P. If low there take a look at your Het Osc input. Het Osc serves as the LO for the Mixer and TIF as the RF input. TIF seldom problem but it could be. Output at MD is the actual transmit frequency which will be Het minus TIF. Should have about 1 volt of Het at TP-3. If low try adjusting the Het Osc coil. Make sure you peak it on slow side of the response curve and back off a little.

> > > > > > 43 x 1.414 = 60.8 peak rf volts
> > > > > > 60.8 - 51.4 vdc bias = 9.4 volts difference. This is reason why I have FSD ALC indication. It is normal to require more Car Level voltage on 10 meters. If unsure just set it Full CW to start with.
> > > > > >
> > > > > > -51.4/1.414 = 36.0 rf volts. You must have greater than 36.0 rf volts at -51.4vdc operating bias to get any ALC indication. The Rf drive signal must make the 6146 control grid positive with respect to the cathode so that ua grid current flows to produce any ALC indication. The greater the delta between dc bias and RF drive voltage on positive swing of the RF envelope the higher the ALC deflection will be.
> > > > > >
> > > > > > So you need to load your rig on 10 meters into dummy load. Since you have no ALC indication use a workaround like peaking the Drive Control on receiver back ground noise or use the Marker. After loading to full load flip the SG switch off and make the RF drive and DC bias voltage measurements on the 6146 control grid as I did above.

> > > > > > > > I do not doubt that you have no ALC indication on 10 meters on your TS-520. In my experience it is "common", but not "normal". I would also be very careful citing and observing any of these "service bulletins". I am very skeptical of most of these as some are just flat wrong. Putting star lock washers on circuit board to cure VFO drift isnt first thing I will ever reach for! They appear to me to be nothing more than a list of one line anecdotal entries submitted by owners and perhaps Kenwood service center bench techs? One line entries with no details, no basis, no explanations are not what I would expect from a factory authorized service bulletin.
> > > > > > > >
> > > > > > > > I have worked on probably 30 or so TS520s in a 10 year period. Not an exhaustive number, but enough to know that all but one left my bench with adequate ALC indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.
> > > > > > > >
> > > > > > > > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of

the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> > > > > > > >
> > > > > > > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > > > > > >

Adrian,

Another good way of loosening the slug is to get nice clean soler iron and place hot tip onto slug and allow to heat, then turn immediately the iron has been removed from slug, sorks everytime for me.

Subject: [TS-520_820_530_830] Re: Progress report new 520SE acquisition

Hi Adrian:

1. You dont need any ALC indication to adjust the 10 meter drive coil. Set the Drive Control to 1200 then use an RF probe/VTVM/DMM, O-scope, or RF Millivolt meter to peak the RF drive at the Plate of Driver Tube or at the Control Grids of the 6146 finals. If you have a single diode RF probe best to just monitor the RF voltage at the finals control grid. Just set Car Level pot to full CW to ensure you have good TIF level.

2. Did you set the VFO dial to zero (15.0mhz) to see the Marker signal on the S-meter to peak the WWV coils? Tune the VFO for max S-meter indication. You then peak signal with T4 and T5 for max S-meter indication and then adjust T3 for max S-meter indication and then back off T3 1/4 turn CCW. A better way is to use a RF sig generator and inject a 15 mhz signal into the SO-239 connector. I usually start with a -73dBm or 50.0 uv signal level and reduce the sig gen level as I get the tuned circuits peaked.

Putting star lock washers on circuit board to cure VFO drift isnt

first thing I will ever reach for! They appear to me to be nothing more than a list of one line anecdotal entries submitted by owners and perhaps Kenwood service center bench techs? One line entries with no details, no basis, no explanations are not what I would expect from a factory authorized service bulletin.
> > > > > > > >
> > > > > > > > > I have worked on probably 30 or so TS520s in a 10 year period. Not an exhaustive number, but enough to know that all but one left my bench with adequate ALC indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.
> > > > > > > >
> > > > > > > > > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> > > > > > > >
> > > > > > > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > > > > > >
> > > > > > > > > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.
> > > > > > > >
> > > > > > > > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
> > > > > > > >

> > > > > > > > There is a reason that you may have no ALC indication in CW Mode at 200 ma Ip and it has to do with degenerative RF feedback, but I wont go into it in this response.

> > > > > > > > > If you want to work on your no ALC indication on 10 meters start with a fresh 12BY7A and make sure you have spec DC voltages and make sure your cathode resistors are all at design value.
> > > > > > > > >
> > > > > > > > > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.
> > > > > > > >
> > > > > > > > > Not just my experience. You might contact Jimmy Lamanteer WB2KNR who still operates his original dealer purchased new TS520 as his main rig and collects them and has 8 or 10 at all times and he reports to me that they all have some level of ALC indication on 10 meters.

Hi Terry,

Thanks for suggestions - I've had a really productive morning here working on the rig!

Took your idea of measuring th DP voltage, but I was finding that e scope was detuning the driver - with the probe off the ALC peak position (for Drive control) was way off what it was when peaking drive coil using scope.

But I still worked through bands and peaked using scope trace (all slugs moving on Drive coil board). I noticed that on some bands I could get a healthy p-p voltage but with probe off see no alc unless I moved Drive a long way off 12 o'clock. So I tried peaking again from start in correct sequence but using alc meter. This time when I moved the 28MHz slug way up towards top of former I got a really healthy ALC! In fact I realised that the slug had been almost at bottom of former (normal position for 1.8 Drive slug) but manual says otherbslugs should be near top end. Anyway I can now get full scale ALC on 10m with carrier at about 1 o'clock, and indicated 80 W out on a pretty accurate Welz meter I have. Brilliant!

As I had slugs moving nicely I peaked all the receive circuits. Got another couple or so s points on each band, but the best thing is the Drive control is now aligned from Rx to Tx - peaking alc with drive is where peak receive noise is for that frequency. Also everything is happening around the 12 o'clock position, whereas before I had to move a long way off centre, and 14MHz was actually running out of room before alc peak.

I still get no s reading in WWV position but can hear calibrator (but not strongly). The manual is a bit confusing on WWV circuit descriptions - I'm sure some of the transistors numbers they reference do not match block diagram. I put scope on collector of Q8 on RF which I think is wwv oscillator, and just get a messy very low amplitude signal. But when I hook up to antenna the s meter moves a bit (S5 or so) if I tune up from 15MHz and hit a broadcast station, so does that mean the WWV oscillator is running? Adjusting wwv coils on rf board makes no diffence to zero S meter reading, but tweaking T4 and T5 peaks the faint calibrator noise.

WWV receive is a minor thing - delighted to have proper ALC on 10m and properly aligned rig.

Thanks again for getting me this far and convincing me that the "no alc is normal" is a myth!

73 Adrian G4IQW

> 1. You dont need any ALC indication to adjust the 10 meter drive coil. Set the Drive Control to 1200 then use an RF probe/VTVM/DMM, O-scope, or RF Millivolt meter to peak the

RF drive at the Plate of Driver Tube or at the Control Grids of the 6146 finals. If you have a single diode RF probe best to just monitor the RF voltage at the finals control grid. Just set Car Level pot to full CW to ensure you have good TIF level.
>
> 2. Did you set the VFO dial to zero (15.0mhz) to see the Marker signal on the S-meter to peak the WWV coils? Tune the VFO for max S-meter indication. You then peak signal with T4 and T5 for max S-meter indication and then adjust T3 for max S-meter indication and then back off T3 1/4 turn CCW. A better way is to use a RF sig generator and inject a 15 mhz signal into the SO-239 connector. I usually start with a -73dBm or 50.0 uv signal level and reduce the sig gen level as I get the tuned circuits peaked.

> > I found a really strange thing when going through the manual. When I tried to peak WWV frequency I couldn't, as though I could hear the calibrator signal I had no s-meter deflection on that band switch position. On 14MHz position I don't get s-meter deflection unless I peak with Drive control, but the Drive control is not operative on WWV so it may be same thing on WWV. I don't want to mess with T4, T5 and T3 on the RF board with no s-meter to guide me. Any suggestions?

It's a slight improvement on how it was tracking before, and if Inuse calibrator again at 600 end then it's spot on. Without recalibrating against marker I can get it to 5.5000 at 0 end and 4.9004 at 600 end which will do for me.

exhaustive number, but enough to know that all but one left my bench with adequate ALC
indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy
and owner was in a hurry to get it back. In my experience can typically get at least 1/2
scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC
indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when
I got it.
> > > > > > > > >
> > > > > > > > > > I once had a fellow call me(some how got my home phone) and he was mad as
hell. He told me he saw where I responded on some forum just as I am to you and that he had
purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of
the box and he called Kenwood and they told him it was "normal". Now I dont want to call
anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design
engineer in Japan. If so what did that engineer say was the reason? Would there not have
been a discussion and some additional probing questions? I suggested that perhaps he had
called the dealer and maybe even talked to a dealer bench tech who said something like " I
see that all the time". Very different from a design engineer explaining why it was

"normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> > > > > > > > >
> > > > > > > > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > > > > > > >
> > > > > > > > > > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.
> > > > > > > > >
> > > > > > > > > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
> > > > > > > > >

> > > > > > > > > >
> > > > > > > > > > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.

Thanks Dave I was trying this (Keith Hutt also gave me this tip) but had no luck. Maybe I wasn't quick enough moving slug after removing iron tip? Didn't realise had to try to move it immediately.

Penetrant (tri-flo equivalent from model shop) did trick once I applied with brush round outside of slug, and allowed it to work its way down threads. All my coils on all oards moving except for the one cracked one I had on 3.5MHz het coil.

Set the Drive Control to 1200 then use an RF probe/VTVM/DMM, O-scope, or RF Millivolt meter to peak the RF drive at the Plate of Driver Tube or at the Control Grids of the 6146 finals. If you have a single diode RF probe best to just monitor the RF voltage at the finals control

grid. Just set Car Level pot to full CW to ensure you have good TIF level.
>
> 2. Did you set the VFO dial to zero (15.0mhz) to see the Marker signal on the S-meter to peak the WWV coils? Tune the VFO for max S-meter indication. You then peak signal with T4 and T5 for max S-meter indication and then adjust T3 for max S-meter indication and then back off T3 1/4 turn CCW. A better way is to use a RF sig generator and inject a 15 mhz signal into the SO-239 connector. I usually start with a -73dBm or 50.0 uv signal level and reduce the sig gen level as I get the tuned circuits peaked.

> > I found a really strange thing when going through the manual. When I tried to peak WWV frequency I couldn't, as though I could hear the calibrator signal I had no s-meter deflection on that band switch position. On 14MHz position I don't get s-meter deflection unless I peak with Drive control, but the Drive control is not operative on WWV so it may be same thing on WWV. I don't want to mess with T4, T5 and T3 on the RF board with no s-meter to guide me. Any suggestions?

It's a slight improvement on how it was tracking before, and if Inuse calibrator again at 600 end then it's spot on. Without recalibrating against marker I can get it to 5.5000 at 0 end and 4.9004 at 600 end which will do for me.

P-P that your scope will display.
> > > >
> > > > Probably easiest is to take a look at Transmit Mixer output at the MD terminal or I believe you also have a TP-1 on the RF board. Should see something close to 2 rms volts or 6 volts P-P. If low there take a look at your Het Osc input. Het Osc serves as the LO for the Mixer and TIF as the RF input. TIF seldom problem but it could be. Output at MD is the actual transmit frequency which will be Het minus TIF. Should have about 1 volt of Het at TP-3. If low try adjusting the Het Osc coil. Make sure you peak it on slow side of the response curve and back off a little.

> > > > > > > 60.8 - 51.4 vdc bias = 9.4 volts difference. This is reason why I have FSD ALC indication. It is normal to require more Car Level voltage on 10 meters. If unsure just set it Full CW to start with.
> > > > > > >
> > > > > > > -51.4/1.414 = 36.0 rf volts. You must have greater than 36.0 rf volts at -51.4vdc operating bias to get any ALC indication. The Rf drive signal must make the 6146 control grid positive with respect to the cathode so that ua grid current flows to produce any ALC indication. The greater the delta between dc bias and RF drive voltage on positive swing of the RF envelope the higher the ALC deflection will be.
> > > > > > >
> > > > > > > So you need to load your rig on 10 meters into dummy load. Since you have no ALC indication use a workaround like peaking the Drive Control on receiver back ground noise or use the Marker. After loading to full load flip the SG switch off and make the RF drive and DC bias voltage measurements on the 6146 control grid as I did above.

Adrian: Good Job!

I am glad you have good ALC indication on 10 meters now. As I told you this business about it being "Normal" is a tribal myth. It is far too "Common" and generally can be corrected in my experience. I am working on a "white paper" that addresses the 10 meter TX and RX design compromises and things you can do. When done will talk to Gordon about placing in the Files section for all to use.

Yes the scope can de-tune when you are measuring RF drive levels. Most scopes are 1 meg input and the input capacitance is the thing that gets you so you need to use a low capacitance probe and it is normal to have to repeak the Drive control as you found it will not peak at 1200. This is one of reasons I use a Boonton RF Millivolt meter. Its input Z has far less loading affect and just easier and faster to use.

Regards WWV you are not adjusting anything to zero the S meter. You are adjusting to peak the S meter indication. I would not get on Q8 oscillator collector. Too easy to pull the oscillator. The output of Q8 Het Osc is the emitter and they use a 5pf cap to couple this output to Mixer Q4. I have never measured the Het Osc level at input of Q4 so cant tell you what normal level is. Most mixers require high level LO signal so would not be surprised to find approx 1.0 rf volts. There is no tank circuit that you can peak the oscillator level. You might try looking at the RIF Terminal post with your scope and peak T5, T4, and T3 for maximum P-P level with bandswitch at 15mhz with Marker on or 15 mhz injected into SO-239 as I previously noted.

Terry K9TW

>
>
>
> I still get no s reading in WWV position but can hear calibrator (but not strongly). The manual is a bit confusing on WWV circuit descriptions - I'm sure some of the transistors numbers they reference do not match block diagram. I put scope on collector of Q8 on RF which I think is wwv oscillator, and just get a messy very low amplitude signal. But when I hook up to antenna the s meter moves a bit (S5 or so) if I tune up from 15MHz and hit a broadcast station, so does that mean the WWV oscillator is running? Adjusting wwv coils on rf board makes no diffence to zero S meter reading, but tweaking T4 and T5 peaks the faint calibrator noise.

Set the Drive Control to 1200 then use an RF probe/VTVM/DMM, O-scope, or RF Millivolt meter to peak the RF drive at the Plate of Driver Tube or at the Control Grids of the 6146 finals. If you have a single diode RF probe best to just monitor the RF voltage at the finals control grid. Just set Car Level pot to full CW to ensure you have good TIF level.
> >
> > 2. Did you set the VFO dial to zero (15.0mhz) to see the Marker signal on the S-meter to peak the WWV coils? Tune the VFO for max S-meter indication. You then peak signal with T4 and T5 for max S-meter indication and then adjust T3 for max S-meter indication and then back off T3 1/4 turn CCW. A better way is to use a RF sig generator and inject a 15 mhz signal into the SO-239 connector. I usually start with a -73dBm or 50.0 uv signal level and reduce the sig gen level as I get the tuned circuits peaked.

> > > > > > 60.8 - 51.4 vdc bias = 9.4 volts difference. This is reason why I have FSD ALC indication. It is normal to require more Car Level voltage on 10 meters. If unsure just set it Full CW to start with.
> > > > > > >
> > > > > > -51.4/1.414 = 36.0 rf volts. You must have greater than 36.0 rf volts at -51.4vdc operating bias to get any ALC indication. The Rf drive signal must make the 6146 control grid positive with respect to the cathode so that ua grid current flows to produce any ALC indication. The greater the delta between dc bias and RF drive voltage on positive swing of the RF envelope the higher the ALC deflection will be.
> > > > > > >
> > > > > > So you need to load your rig on 10 meters into dummy load. Since you have no ALC indication use a workaround like peaking the Drive Control on receiver back ground noise or use the Marker. After loading to full load flip the SG switch off and make the RF drive and DC bias voltage measurements on the 6146 control grid as I did above.

I would also be very careful citing and observing any of these "service bulletins". I am very skeptical of most of these as some are just flat wrong. Putting star lock washers on circuit board to cure VFO drift isnt first thing I will ever reach for! They appear to me to be nothing more than a list of one line anecdotal entries submitted by owners and perhaps Kenwood service center bench techs? One line entries with no details, no basis, no explanations are not what I would expect from a factory authorized service bulletin.

> > > > > > > > > >
> > > > > > > > > > > I have worked on probably 30 or so TS520s in a 10 year period. Not an exhaustive number, but enough to know that all but one left my bench with adequate ALC indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.
> > > > > > > > > >
> > > > > > > > > > > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> > > > > > > > > >
> > > > > > > > > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > > > > > > > >
> > > > > > > > > > > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.
> > > > > > > > > >
> > > > > > > > > > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
> > > > > > > > > >
> > > > > > > > > > > There is a reason that you may have no ALC indication in CW Mode at 200 ma Ip and it has to do with degenerative RF feedback, but I wont go into it in this response.

> > > > > > > > > > > Sorry so long, but this is not easy subject to cover briefly.
> > > > > > > > > > >
> > > > > > > > > > > If you want to work on your no ALC indication on 10 meters start with a fresh 12BY7A and make sure you have spec DC voltages and make sure your cathode resistors are all at design value.
> > > > > > > > > > >
> > > > > > > > > > > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.
> > > > > > > > > >
> > > > > > > > > > > Not just my experience. You might contact Jimmy Lamanteer WB2KNR who still operates his original dealer purchased new TS520 as his main rig and collects them and has 8 or 10 at all times and he reports to me that they all have some level of ALC indication on 10 meters.

Hi Terry

Sorry I wasn't clear - was trying to say tweaking those transformers made no difference to s meter reading zero with audible calibrator signal beat, not that I was aiming to zero meter!

Thanks for pointers on wwv oscillator. I'll check those het readings and look at RIF signal.

The scope probe I was trying to use has 12pf capacitance in x10 position, and is described ad a probe for up to 50 MHz. Maybe that 12pf just too much? Not an issue now I have good ALC!

73 Adrian G4IQW

>
> Adrian: Good Job!
>
> I am glad you have good ALC indication on 10 meters now. As I told you this business about it being "Normal" is a tribal myth. It is far too "Common" and generally can be corrected in my experience. I am working on a "white paper" that addresses the 10 meter TX and RX design compromises and things you can do. When done will talk to Gordon about placing in the Files section for all to use.
>
> Yes the scope can de-tune when you are measuring RF drive levels. Most scopes are 1 meg input and the input capacitance is the thing that gets you so you need to use a low capacitance probe and it is normal to have to repeak the Drive control as you found it will not peak at 1200. This is one of reasons I use a Boonton RF Millivolt meter. Its input Z has far less loading affect and just easier and faster to use.
>
> Regards WWV you are not adjusting anything to zero the S meter. You are adjusting to peak the S meter indication. I would not get on Q8 oscillator collector. Too easy to pull the oscillator. The output of Q8 Het Osc is the emitter and they use a 5pf cap to couple this output to Mixer Q4. I have never measured the Het Osc level at input of Q4 so cant tell you what normal level is. Most mixers require high level LO signal so would not be surprised to find approx 1.0 rf volts. There is no tank circuit that you can peak the oscillator level. You might try looking at the RIF Terminal post with your scope and peak T5, T4, and T3 for maximum P-P level with bandswitch at 15mhz with Marker on or 15 mhz injected into SO-239 as I previously noted.

> >
> >
> >
> > I still get no s reading in WWV position but can hear calibrator (but not strongly). The manual is a bit confusing on WWV circuit descriptions - I'm sure some of the transistors numbers they reference do not match block diagram. I put scope on collector of Q8 on RF which I think is wwv oscillator, and just get a messy very low amplitude signal. But when I hook up to antenna the s meter moves a bit (S5 or so) if I tune up from 15MHz and hit a broadcast station, so does that mean the WWV oscillator is running? Adjusting wwv coils on rf board makes no diffence to zero S meter reading, but tweaking T4 and T5 peaks the faint calibrator noise.

> > > > > > > > 60.8 - 51.4 vdc bias = 9.4 volts difference. This is reason why I have FSD ALC indication. It is normal to require more Car Level voltage on 10 meters. If unsure just set it Full CW to start with.
> > > > > > > >
> > > > > > > > -51.4/1.414 = 36.0 rf volts. You must have greater than 36.0 rf volts at -51.4vdc operating bias to get any ALC indication. The Rf drive signal must make the 6146 control grid positive with respect to the cathode so that ua grid current flows to produce any ALC indication. The greater the delta between dc bias and RF drive voltage on positive swing of the RF envelope the higher the ALC deflection will be.

> > > > > > > >
> > > > > > > > > So you need to load your rig on 10 meters into dummy load. Since you have no ALC indication use a workaround like peaking the Drive Control on receiver back ground noise or use the Marker. After loading to full load flip the SG switch off and make the RF drive and DC bias voltage measurements on the 6146 control grid as I did above.

I would also be very careful citing and observing any of these "service bulletins". I am very skeptical of most of these as some are just flat wrong. Putting star lock washers on circuit board to cure VFO drift isnt first thing I will ever reach for! They appear to me to be nothing more than a list of one line anecdotal entries submitted by owners and perhaps Kenwood service center bench techs? One line entries with no details, no basis, no explanations are not what I would expect from a factory authorized service bulletin.
> > > > > > > > > > >
> > > > > > > > > > > > I have worked on probably 30 or so TS520s in a 10 year period. Not an exhaustive number, but enough to know that all but one left my bench with adequate ALC indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when I got it.
> > > > > > > > > > >
> > > > > > > > > > > > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> > > > > > > > > > >
> > > > > > > > > > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > > > > > > > > >
> > > > > > > > > > > > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.

> > > > > > > > > > >
> > > > > > > > > > > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
> > > > > > > > > > >
> > > > > > > > > > > > There is a reason that you may have no ALC indication in CW Mode at 200 ma Ip and it has to do with degenerative RF feedback, but I wont go into it in this response.

> > > > > > > > > > > > > If you want to work on your no ALC indication on 10 meters start with a fresh 12BY7A and make sure you have spec DC voltages and make sure your cathode resistors are all at design value.
> > > > > > > > > > > > >
> > > > > > > > > > > > > Then in order to have ALC indication you need two key voltages. Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.
> > > > > > > > > > >
> > > > > > > > > > > > Not just my experience. You might contact Jimmy Lamanteer WB2KNR who still operates his original dealer purchased new TS520 as his main rig and collects them and has 8 or 10 at all times and he reports to me that they all have some level of ALC indication on 10 meters.

although there are 520 owners who say they do get ALC on 10M.

Topic: 42105 Message: 42645

OK Understood. Yes 12 pf is a bunch at 10 meters. That is part of design challenge for all 10 meter transmit and receive circuit design. The minimum fixed "parasitic" or stray capacitance prevents the engineers from using optimum tuned circuit LC ratios and optimum loaded Q. In the TX circuits they have to use the combination of the Driver tube internal electrode capacitance and the PC trace and bandswitch trace capacitances for the parallel resonant circuits.

I forgot to mention I highly recommend that you now run a set of TX Level Diagrams from the TIF amp input on your RF board to the Finals Control grids. Run then on each band.

Load up to max rf output (100 watts or so without exceeding max of 200 ma Ip) on each band into dummy load. Place ALC indication with Car Level Pot and Drive control peaked at no less than full scale of the black ALC box. Turn off the SG switch and in CW TX mode record the Rf voltage at TIF, MD (transmit Mixer output), DP, and control grid of the 6146 finals. Also at control grid of finals record the dc operating bias voltage level. Log these in your notes for future troubleshooting use.

Terry K9TW

> > I am glad you have good ALC indication on 10 meters now. As I told you this business about it being "Normal" is a tribal myth. It is far too "Common" and generally can be corrected in my experience. I am working on a "white paper" that addresses the 10 meter TX and RX design compromises and things you can do. When done will talk to Gordon about placing in the Files section for all to use.
> >

> > Yes the scope can de-tune when you are measuring RF drive levels. Most scopes are 1 meg input and the input capacitance is the thing that gets you so you need to use a low capacitance probe and it is normal to have to repeak the Drive control as you found it will not peak at 1200. This is one of reasons I use a Boonton RF Millivolt meter. Its input Z has far less loading affect and just easier and faster to use.
> >
> > Regards WWV you are not adjusting anything to zero the S meter. You are adjusting to peak the S meter indication. I would not get on Q8 oscillator collector. Too easy to pull the oscillator. The output of Q8 Het Osc is the emitter and they use a 5pf cap to couple this output to Mixer Q4. I have never measured the Het Osc level at input of Q4 so cant tell you what normal level is. Most mixers require high level LO signal so would not be surprised to find approx 1.0 rf volts. There is no tank circuit that you can peak the oscillator level. You might try looking at the RIF Terminal post with your scope and peak T5, T4, and T3 for maximum P-P level with bandswitch at 15mhz with Marker on or 15 mhz injected into SO-239 as I previously noted.

> > >
> > >
> > >
> > > I still get no s reading in WWV position but can hear calibrator (but not strongly). The manual is a bit confusing on WWV circuit descriptions - I'm sure some of the transistors numbers they reference do not match block diagram. I put scope on collector of Q8 on RF which I think is wwv oscillator, and just get a messy very low amplitude signal. But when I hook up to antenna the s meter moves a bit (S5 or so) if I tune up from 15MHz and hit a broadcast station, so does that mean the WWV oscillator is running? Adjusting wwv coils on rf board makes no diffence to zero S meter reading, but tweaking T4 and T5 peaks the faint calibrator noise.

Set the Drive Control to 1200 then use an RF probe/VTVM/DMM, O-scope, or RF Millivolt meter to peak the RF drive at the Plate of Driver Tube or at the Control Grids of the 6146 finals. If you have a single diode RF probe best to just monitor the RF voltage at the finals control grid. Just set Car Level pot to full CW to ensure you have good TIF level.
> > > >
> > > > 2. Did you set the VFO dial to zero (15.0mhz) to see the Marker signal on the S-meter to peak the WWV coils? Tune the VFO for max S-meter indication. You then peak signal with T4 and T5 for max S-meter indication and then adjust T3 for max S-meter indication and then back off T3 1/4 turn CCW. A better way is to use a RF sig generator and inject a 15 mhz signal into the SO-239 connector. I usually start with a -73dBm or 50.0 uv signal level and reduce the sig gen level as I get the tuned circuits peaked.

> > > > >
> > > > >
> > > > > I found a really strange thing when going through the manual. When I tried to peak WWV frequency I couldn't, as though I could hear the calibrator signal I had no s-meter deflection on that band switch position. On 14MHz position I don't get s-meter deflection unless I peak with Drive control, but the Drive control is not operative on WWV so it may be same thing on WWV. I don't want to mess with T4, T5 and T3 on the RF board with no s-meter to guide me. Any suggestions?

It's a slight improvement on how it was tracking before, and if Inuse calibrator again at 600 end then it's spot on. Without recalibrating against marker I can get it to 5.5000 at 0 end and 4.9004 at 600 end which will do for me.

> > > > > > > >
> > > > > > > Probably easiest is to take a look at Transmit Mixer output at the MD terminal or I believe you also have a TP-1 on the RF board. Should see something close to 2 rms volts or 6 volts P-P. If low there take a look at your Het Osc input. Het Osc serves as the LO for the Mixer and TIF as the RF input. TIF seldom problem but it could be. Output at MD is the actual transmit frequency which will be Het minus TIF. Should have about 1 volt of Het at TP-3. If low try adjusting the Het Osc coil. Make sure you peak it on slow side of the response curve and back off a little.

I would also be very careful citing and observing any of these "service bulletins". I am very skeptical of most of these as some are just flat wrong. Putting star lock washers on circuit board to cure VFO drift isnt first thing I will ever reach for! They appear to me to be nothing more than a list of one line anecdotal entries submitted by owners and perhaps Kenwood service center bench techs? One line entries with no details, no basis, no explanations are not what I would expect from a factory authorized service bulletin.
> > > > > > > > > > >
> > > > > > > > > > > I have worked on probably 30 or so TS520s in a 10 year period. Not an exhaustive number, but enough to know that all but one left my bench with adequate ALC indication on 10 meters. That one would get approx 1/4 scale deflection and was very touchy and owner was in a hurry to get it back. In my experience can typically get at least 1/2 scale deflection with Car Level pot at 1400 to 1500 position. My own personal TS-520 ALC indication on 10 meters is a little bit better than 1/2 scale deflection. It had none when

I got it.
> > > > > > > > > > > >
> > > > > > > > > > > > > I once had a fellow call me(some how got my home phone) and he was mad as hell. He told me he saw where I responded on some forum just as I am to you and that he had purchased his TS520 new from big west coast dealer and it had no ALC on 10 meters out of the box and he called Kenwood and they told him it was "normal". Now I dont want to call anyone a liar, but I suggested that I doubted he had actually called Kenwood factory design engineer in Japan. If so what did that engineer say was the reason? Would there not have been a discussion and some additional probing questions? I suggested that perhaps he had called the dealer and maybe even talked to a dealer bench tech who said something like " I see that all the time". Very different from a design engineer explaining why it was "normal". I then suggested that had it been me I would have taken the rig back to dealer and told them when they can sell me a new in the box one that has ALC indication on all bands I will take it. He was fuming by time conversation ended.
> > > > > > > > > > > >
> > > > > > > > > > > > > I closed the conversation this way. The compelling question you need to ask yourself is....."IF ONE OR MORE TS-520 HAVE SOME LEVEL OF ALC INDICATION ON 10 METERS WHY CANNOT ALL"? If later serial number production runs did not have this problem, wouldnt a mod have been issued? I know of no such Kenwood fix.
> > > > > > > > > > > >
> > > > > > > > > > > > > Would Ford make a car that the speed-o-meter worked in 1st, 2nd, and 3rd gear, but in 4th gear you had to use some kind of work around to tell how fast your were going (maybe timing mile marker post with your wrist watch)? Would customers really live with that and call it normal? I dont think so.
> > > > > > > > > > > >
> > > > > > > > > > > > > Also the manual does not say it is normal. I get that thrown at me. The operating manual clearly states that "Note: If there is no ALC reading indicated, increase the CAR control until there is an ALC reading" There is no disclaimer that follows that says "with the exception of on 10 meters". I think what confuses people is the statement later under the CW loading that says at 200 ma of Ip there may be no ALC indication. Too bad Kenwood had to make that statement, but apparently people were loading rig for max RF output using the RF detector position and for some odd reason then flipping meter back to ALC position instead of back to Ip. Maybe old timers who were use to loading the old Class C CW grid leak bias transmitters? Maybe they thought they needed to check and re-peak grid current? A Class AB1 Kenwood doesnt operate that way. We have essentially no grid current and no reason to keep checking ALC indication in the loading procedure. I dont understand it. Kenwood even followed this note by adding a chart that shows the preferred meter positions and it clearly shows that you should use Ip position when loading in CW. At 200 ma you are done and no reason to see if ALC has fallen off.
> > > > > > > > > > > >
> > > > > > > > > > > > > There is a reason that you may have no ALC indication in CW Mode at 200 ma Ip and it has to do with degenerative RF feedback, but I wont go into it in this response.

> > > > > > > > > > > > > If you want to work on your no ALC indication on 10 meters start with a fresh 12BY7A and make sure you have spec DC voltages and make sure your cathode resistors are all at design value.
> > > > > > > > > > > >
> > > > > > > > > > > > > Then in order to have ALC indication you need two key voltages.

Start by checking your 6146 control grid Pin 5 operating DC bias voltage with 60 ma resting plate current. Also measure your RF drive voltage. If one or both of these are not to spec on 10 meters you will have no ALC indication. Need to be able to accurately measure these with a calibrated RF millivolt meter or O-scope. If you have -55vdc operating bias then you will need greater than 55/1.414 = 38.89 rms or 110.4 P-P rf drive volts. At 39 rf volts you will have just barely overcome the DC bias offset. The control grid of the 6146 must go positive on the positive half of the RF drive envelope in order for Ua grid current to flow. If 6146 control grid never goes positive relative to the cathode then there will be no Ua grid current. No Ua grid current means no ALC indication. This is the first place to start.
> > > > > > > > > > > >
> > > > > > > > > > > > > Not just my experience. You might contact Jimmy Lamanteer WB2KNR who still operates his original dealer purchased new TS520 as his main rig and collects them and has 8 or 10 at all times and he reports to me that they all have some level of ALC indication on 10 meters.

Hi All

When i switch the mode switch from lsb to usb or cw the digital dial and receiver cuts out. It works fine in lsb and i can hear the relay cut in when i switch to usb,but no dial or audio
help

Don,

What hybrid transceiver are you having trouble with?

42650. TS-530s Question

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-08 18:58:46 UTC
From: ThomasA
Topic: 42650 Message: 42650

Hello all,

My setup consists of a TS530s, and a 20m dipole in an inverted V configuration.

I finally purchased an antenna analyzer, and intended to use it to trim my antenna and improve efficiency.

My first readings indicated an average SWR of 1:2.4 across the phone portion of the 20 meter band, after using the analyzer, and some trimming I was able to lower it to an average of 1:1.4, so I was happy.

However now when I go through my tuning procedure the "dip" on my plate occurs when the pointer is in the 12 or 15 meter portion of the dial, when before it was in the 20m portion, where I assume it should be.

I tune into a oil filled dummy load.

Any ideas? did I foul something up? Do I have a problem with my radio and the timing is just a coincidence?

I would appreciate any input

Tom KC0ZRV

Tom,

Do you have an SWR meter to put in line? I would try that next. If the SWR is higher than the analyzer said then adjust the ends so the SWR drops to the lowest value. You can wrap any excess wire at both end of the dipole/inverted vee, along the ends. Wrapping the excess wire along the ends of the antenna will not affect the SWR and the performance and loading of the antenna.

If the antenna is built and erected properly, away from surrounding objects, then you should be able to adjust the length of both side equally, then use a separate SWR meter and obtain a very low SWR. I typically adjust the ends so the SWR is lowest at the middle of the band. This will allow you to operate over the entire band without having a significant increase in SWR. This is true for all bands except 80 where the typical bandwidth of a dipole is 25Khz to 30Khz before SWR reaches an unacceptable level.

Mike:

Wonder what license he holds? Not sure I understand his goal.

At what frequency should he trim it for resonance with his SWR bridge?

I thought he was trying to get it reasonably flat in the phone portion of the 20 meter band. If that is true then should he be loading at approx 14.250mhz and measuring his SWR there for starters?

The analyzer should have told him where resonance was and then easy to tell if need to add or shorten. I think you and I always leave long and easier to trial shorten by wrapping as you point out.

I dont know where he is loading at to get the Tank Cap to be pointing at 15 meters. He has less capacitance for resonance so sounds like antenna is too short?

Are you saying the digital display goes blank and receiver goes dead when you place mode switch to USB?

If so sounds like you have lost USB Carrier Osc signal on PLL board. Need Carrier oscillator input to Mixer Q40 to have digital display and need Carrier oscillator output from PLL board to IF board for receive.

If you are familiar with PLL board go to Conn 8 Pin 5 and see if you have approx 9vdc when you place mode switch in USB position. Can gently wiggle Conn 8.

If you have 9vdc at Pin 5 then possible you have a bad USB crystal. I have never seen a bad one. You could gently tap on case with pencil eraser. You could adjust Trimmer Capacitor TC-3 on PLL board.

OK Don keep us informed. Be aware that you have HV filter caps with 900vdc on them in close proximity to the PLL board. Control any alligator or mini-grabber test leads that you may use so wont accidently flop into the capacitors. I would leave rig on its side with the PLL board oriented down to lessen chance of this.

Yes very good advice
Will let you know for sure
Thanks Again

I need some help with a ts830s I picked up at the Plano, TX Ham-Com. When I plugged it up there was no output, I have 930 volts on the HV No bias voltagesh i suspected the tubes, 6146B's I observed a small amount of smoke in the area of board X44-1360-00. I immediately shut the rig down. After opening up the tank circuit enclosure I found that both V1 and V2 were defective with holes in the plates and V2's glass envelope was shattered at the base. I removed them both and restarted the rig to run voltage tests on V1 & V2. I have 12.8 vac on V1 pin 2, pin 3 has 131 vdc, pins 1, 4 & 6 have no voltage and pin 5 also has no voltage.

Any ideas where and what to look for next while waiting on new tubes? I don.t want to put in the next set of tubes without insuring theywill noy be damaged too.

Also, should this become too involved for my capabilities can anyone suggest a good repairman inthe East Texas ar

Thanks
Barry KF5GC

If I trimmed too much from the antenna would that make the point at which I get the "dip" when tuning? the lowest SWR is at 14.255, according to the analyzer.

Before, when I went through the tuning procedure, the pointer was in the range of 20m. Now when the "dip" occurs the pointer is in either the 12m or the 15m range.

It is just different than it was before, and I am just trying to understand it.

Are you saying that the plate dip has changed when tuning into the 50 Ohm load? Obviously, then this has nothing to do with the antenna. BTW, by definition, the denominator of VSWR is always 1- i.e. VSWR is always expressed as a number greater than or equal to 1.

Subject: [TS-520_820_530_830] TS-530s Question

Hello all,

My setup consists of a TS530s, and a 20m dipole in an inverted V configuration.

I finally purchased an antenna analyzer, and intended to use it to trim my antenna and improve efficiency.

My first readings indicated an average SWR of 1:2.4 across the phone portion of the 20 meter band, after using the analyzer, and some trimming I was able to lower it to an average of 1:1.4, so I was happy.

However now when I go through my tuning procedure the "dip" on my plate occurs when the pointer is in the 12 or 15 meter portion of the dial, when before it was in the 20m portion, where I assume it should be.

I tune into a oil filled dummy load.

Any ideas? did I foul something up? Do I have a problem with my radio and the timing is just a coincidence?

I would appreciate any input

Tom KC0ZRV

Hi Terry
I got lucky.Took a wooden handle from a small paint brush and tapped on
all the connectors and nothing happened
I went to tap on TC-3[gently]and i guess i touched X3 too,and i found
X3[crystal] for some reason to be lose.
I will have to remove the board and desolder it to see what is the cause
as i can wiggle it.
If i keep a bit of downward pressure on X3 all is ok

Hope i explained it ok

OK Don:

After you pull the board just look at both crystals under magnification and see if you can see any pin movement at the solder pads as you gently rock the crystals. You may want to remove solder and re-solder instead of just trying to reheat? Just be careful not to apply too much heat for too long.

If you have a RF probe and VTVM, O-scope, or RF Millivolt meter suggest you measure the RF voltage level at Conn 7 Pin 1 or at TP-3 on the IF board. It should be close to 300mv rms in USB and LSB modes.

Subject: [TS-520_820_530_830] Re: Dial cut out

OK Don:

After you pull the board just look at both crystals under magnification and see if you can see any pin movement at the solder pads as you gently rock the crystals. You may want to remove solder and re-solder instead of just trying to reheat? Just be careful not to apply too much heat for too long.

If you have a RF probe and VTVM, O-scope, or RF Millivolt meter suggest you measure the RF voltage level at Conn 7 Pin 1 or at TP-3 on the IF board. It should be close to 300mv rms in USB and LSB modes.

Terry
yes i think it's the pad.Will let you know how i make out
By the way i have a YK88SN filter.Would it be worth putting it in? or
better to stay with the stock filter.
Appreciate your help

OK what was that SWR at 14.255mhz? What was it at 14.175mhz and at 14.350mhz? As Mike suggested do you have a SWR meter or wattmeter that you can then check the SWR at 14.255mhz to see if close to what your analyzer read?

Also W4OP has a good question. Are you saying that your Plate Tuning capacitor is at or near the 14mhz white mark scribed on your front panel when loading into your dummy load and at or near 21mhz when loading in to the antenna?

If near 14 mhz mark into dummy load it suggests your dummy load is close to 50 ohms resistive. If not near 14 mhz into antenna it suggest antenna is not resistive at 14.255mhz and is presenting some reactive component either Xc or Xl depending on if too short or too long at 14.255mhz.

The beauty of the analyzer is it tells you were it is resonant at and from that you can tell if too long or too short depending on where you want to operate. It will also tell you how broad band the dipole is and a conventional dipole is not very broad banded. It would not be unusual to have 1:2 to 1 at resonance (14.255mhz) and 2:1 at each end of the phone band. As Mike indicated many factors including apex height, nearby objects, apex angle, height of the ends etc. affect the SWR.

If your analyzer measured a VSWR of approx 1.05 to 1.10 to 1 at 14.255mhz then antenna and dummy load should be close to same impedance and Plate Tuning cap should be close to same scribed mark.

Have you measured your dummy load resistor with ohm meter? Or your analyzer? If Cantenna may be a little off of 50 ohms and that is no problem.

Ok, got that backwards. Started with 2.4:1 trimmed went down to 1.4:1

If you look at your 830 manual you will see the recommended filters to make the best use of your VBT control. I personally do not want to listen to 1.8khz wide SSB filter all the time. Whenever band gets crowded you can always adjust VBT to tighten the pass band. With narrower filter you cannot open it up.

Suggest others respond to this. My ear says no and I like full range of my VBT control.

Since you have the filter you can try it just be careful removing the IF board molex connectors and soldering in the filter. Sometimes the pads have been heated multiple times with multiple filter change outs.

Also – you might do a quick test of your dummy load to be sure that it's really resistive at 14 Mhz. Just connect your antenna analyzer directly to your dummy load. The antenna analyzer should show an SWR of 1:1 (or nearly so) and an impedance of 50 ohms (maybe plus or minus 1 ohm) at all frequencies below 30 Mhz. If it's really a good dummy load, it will show an SWR of 1:1 all the way to at least 200 Mhz.

Subject: [TS-520_820_530_830] Re: TS-530s Question

OK what was that SWR at 14.255mhz? What was it at 14.175mhz and at 14.350mhz? As Mike suggested do you have a SWR meter or wattmeter that you can then check the SWR at 14.255mhz to see if close to what your analyzer read?

Also W4OP has a good question. Are you saying that your Plate Tuning capacitor is at or near the 14mhz white mark scribed on your front panel when loading into your dummy load and at or near 21mhz when loading in to the antenna?

If near 14 mhz mark into dummy load it suggests your dummy load is close to 50 ohms resistive. If not near 14 mhz into antenna it suggest antenna is not resistive at 14.255mhz and is presenting some reactive component either Xc or Xl depending on if too short or too long at 14.255mhz.

The beauty of the analyzer is it tells you were it is resonant at and from that you can tell if too long or too short depending on where you want to operate. It will also tell you how broad band the dipole is and a conventional dipole is not very broad banded. It would not be unusual to have 1:2 to 1 at resonance (14.255mhz) and 2:1 at each end of the phone band. As Mike indicated many factors including apex height, nearby objects, apex angle, height of the ends etc. affect the SWR.

If your analyzer measured a VSWR of approx 1.05 to 1.10 to 1 at 14.255mhz then antenna and dummy load should be close to same impedance and Plate Tuning cap should be close to same scribed mark.

Have you measured your dummy load resistor with ohm meter? Or your analyzer? If Cantenna may be a little off of 50 ohms and that is no problem.

well trtied to send it direct but didnt work/ i have an old sylvania 134 that works and has a 3 volt rf scale /it uses a 1247 tube diode for the detector however i dont have the probe cud i jus use a 1n34 and the rest of the circuitry for an rf probe/ the tube uses 6.3 vac for the cathodeof the detector

I am not familiar with this RF millivolt meter. I do have an HP-410C and it also uses a tube diode in the probe and the tri-ax cable to the probe carries the filament voltage from the meter to the tube. So I assume similar set up with your instrument that the tube diode is mounted in the matching probe.

If you do not have the probe does this mean you do not have the cable and connector to plug into the meter?

Do you have the manual and schematic for the meter and the probe? If so should be able to figure out which pins of the connector on the meter are the 6.3vac filament and which ones are for the rectified RF.

Should be able to use a 1n34 diode probe and connect the output of it to input of your meter. Might have to replace input connector and just abandon the filament lead in place. Might have to play around with scaling resistors to get accurate readings.

Hello All,
I agree, No need of the narrow filter with the VBT unless you are an avid CW operator and enjoy contesting. Uggghhhh. I like wide SSB BW and use VBT if it gets a little crowded. I operate more CW than SSB so I use a 530 with narrow filter for CW. Some of us older fellows have a problem with hearing loss in the higher frequencies and tuning into a particular signal with the narrow filter helps. I would think it is a matter of preference. I would recommend using your 830 without the filter for awhile until you are sure it is what you want. The VBT makes adjustment very easy. I would use it for a little bit. Even with CW the VBT is nice. Enjoy your 830. 73, Don K5HFG

Terry,

I don't knowbut when I build and erect a dipole antenna, I don't use an analyzer. I use a simple SWR meter, some RF power applied to the antennafrom the transmitter (transmitter is tuned upinto a 50 ohm dummy loadfirst), the line for both ends is tied around a couple of rocksthrown over a tree limb, and about 30 to 45 minutes of my time.

I have a 40 meter inverted vee that is hanging from a pine tree limb 28 feet in the air at the center. I would go higher but there are too many limbs in the way. The antenna performs perfectly, low SWR over the entire 40 meterband, no SWR higher than 1.7:1 at both ends of the band and SWR of 1.2:1 at the center of the band. It's fed with RG-8x coax and I can work almost any station I can hear, running no more than 85 watts.I have an amp, an Ameritron AL-811 (3 x 811A) but I only use it when I feel it's necessary which isn't that often. I don't "band hop" using the same antenna. If I want to operate on more than one band I'll put the G5RV (102 foot version) back up, shouldn't take more than an hour to erect it (takes time tounravel the antenna and decide which limbs to use) then I would use a tuner, a Drake MN-2000. I currently do not have any RFI problemsof any kind either in the shack, the laptop I use in the shack, or the house. The only RF problem I have ever had was with an old Regency ECT-106 VHF/UHF crystal scanner. I no longer use it inthe shack. I have 2 other scanners in the shack, one is a Regency Touch K500 VHF/UHF and one is a Regency AM Flight Scanner, none of which have any RF problems.

Mike
Like your comments. I recently put up my first 10-80 meter
vertical after being off the air for 20 years. I bought my first
Antenna Analyzer and wow is it nice after using a SWR meter to tune
antennas for years. It does so much more than an SWR meter, i.e.
measures db loss in the coax, tests the coax and in a few minutes I was
able to graph the SWR curve on all bands and make the adjustments just
one time to tune the antenna where I wanted it. I would highly
recommend using one. I would love to have one of your trees here, but
I live in the desert and there is not one tree over 20 feet high within
a half a mile from my house. Inverted V's are almost impossible to
put up here without a tower. I am in the process of putting my
original (first) TS-820S Transceiver, matching VFO and scope back on the
air. I still have to do a little cleaning up and detailing and then
I'll see if it will still load and put out a good signal. Currently I
have a later model Kenwood that is in use.

Well i guess i shud really feel lucky, i have about twenty vally oaks in my prop line but, have to have my son come shoot arrows up for the four cornered 573 ft loop up about50 foot in the air/ it tunes every band but twenty very well and i just fineess that one a bit and it works also/ but will soon have to moive and lose it/ keep hearing location location location / but 8i think it what we can do with where we are/ hopefully i will be able to do with where i have to go/its the pitts to get old/

I have the 2.4Khz SSB filter in all my Hybird radios, never had the opportunity to use 1.8kHz. Depends on how serious you are and if you want to be able to open up the VBT.

Subject: [TS-520_820_530_830] Re: Dial cut out

If you look at your 830 manual you will see the recommended filters to make the best use of your VBT control. I personally do not want to listen to 1.8khz wide SSB filter all the time. Whenever band gets crowded you can always adjust VBT to tighten the pass band. With narrower filter you cannot open it up.

Suggest others respond to this. My ear says no and I like full range of my VBT control.

Since you have the filter you can try it just be careful removing the IF board molex connectors and soldering in the filter. Sometimes the pads have been heated multiple times with multiple filter change outs.

Tom,

I may have missed a part of the thread, but have you tried tuning into the dummy load or other resonate antenna on different band and then check to see if Plate control is out on all bands?

Subject: Re: [TS-520_820_530_830] Re: TS-530s Question

Also ? you might do a quick test of your dummy load to be sure that it?s really resistive at 14 Mhz. Just connect your antenna analyzer directly to your dummy load. The antenna analyzer should show an SWR of 1:1 (or nearly so) and an impedance of 50 ohms (maybe plus or minus 1 ohm) at all frequencies below 30 Mhz. If it?s really a good dummy load, it will show an SWR of 1:1 all the way to at least 200 Mhz.

Subject: [TS-520_820_530_830] Re: TS-530s Question

OK what was that SWR at 14.255mhz? What was it at 14.175mhz and at 14.350mhz? As Mike suggested do you have a SWR meter or wattmeter that you can then check the SWR at 14.255mhz to see if close to what your analyzer read?

Also W4OP has a good question. Are you saying that your Plate Tuning capacitor is at or near the 14mhz white mark scribed on your front panel when loading into your dummy load and at or near 21mhz when loading in to the antenna?

If near 14 mhz mark into dummy load it suggests your dummy load is close to 50 ohms resistive. If not near 14 mhz into antenna it suggest antenna is not resistive at 14.255mhz and is presenting some reactive component either Xc or Xl depending on if too short or too long at 14.255mhz.

The beauty of the analyzer is it tells you were it is resonant at and from that you can tell if too long or too short depending on where you want to operate. It will also tell you how broad band the dipole is and a conventional dipole is not very broad banded. It would not be unusual to have 1:2 to 1 at resonance (14.255mhz) and 2:1 at each end of the phone band. As Mike indicated many factors including apex height, nearby objects, apex angle, height of the ends etc. affect the SWR.

If your analyzer measured a VSWR of approx 1.05 to 1.10 to 1 at 14.255mhz then antenna and dummy load should be close to same impedance and Plate Tuning cap should be close to same scribed mark.

Have you measured your dummy load resistor with ohm meter? Or your analyzer? If Cantenna may be a little off of 50 ohms and that is no problem.

Mike: Yes but at what frequency are you using reduced power from your transmitter to tune the dipole? I think he needed to hear that in addition to check it with an SWR meter.

It depends on your operating goal. Where do you want it to be resonant at? If you want to use it for SSB and CW then you would do this in middle of the allotted frequency range for the band involved. I think that is what your are saying you do when you build a dipole.

I did that for all my first dipoles early in my ham life using 468/F and making it long and then trimming as you describe.

Today I operate less CW so tend to move resonance point up a little higher. I dont spend endless hours trying to get 1:1 and mess around with fat wire or coaxial flat tops to try to broad band it. The Pi-network in the Hybrids handles the resistance and reactance range of the feedpoint impedance of a half wave dipole just fine. It can however cause your normal scribed marks on the Tank capacitor not to align as you move further up and down from resonance. Nothing to worry about.

That was all I was saying. I did not know what his operational goal was and what he was trying to do. I suspect he is trying to make it as flat as he can for the phone portion of the band.

I should have said that the Plate Tuning (Tank)capacitor indicator may not align if you move up or down frequency much beyond about the 2 to 1 bandwidth points of your resonant dipole or inverted-V. In my experience that would be approx 200 to 300 khz. At those points you are starting to introduce some reactive component that the pi-network must compensate for. As I said previously the hybrid pi-network can handle 2:1 mismatch and you are not going to burn up your final tubes or arc over the loading capacitor.

The tank capacitor position indicator when loading into the resonant frequency of a typical inverted-V should be very close to the position loaded into a nominal 50 ohm resistive dummy load. If anything an inverted-V should present a little lower feedpoint impedance than a dipole at the same height.

So the position difference that is being seen is a puzzle if the SWR of the inverted-V at resonance is in the order of 1:4 to 1.

Again I would confirm this SWR as Mike suggested using a SWR bridge or wattmeter if you have one. Not likely your new analyzer is bad, but a good cross check as well as sweeping your dummy load.

What difference are you seeing in the position of the Plate Loading capacitor for approx 100 watts into the antenna versus into the dummy load?

Terry K9TW

The Pi-network in the Hybrids handles the resistance and reactance range of the feedpoint impedance of a half wave dipole just fine. It can however cause your normal scribed marks on the Tank capacitor not to align as you move further up and down from resonance. Nothing to worry about.

Terry,

I'm sorry, I thought I had that in my response.

After the dipole is cut for the "In the ball park" overall length and the excess wire is wrapped along both ends, I start at the bottom of the band and check SWR then repeat the test at the top of the band. This tells me whether I have to shorten or lengthen the antenna at both ends. It doesn't take much equal change in length at both ends to bring the antenna into resonance for the frequency one will be operating at. If one does it enough times it becomes easy and doesn't take long at all to complete.

42684. Re: TS-530s Question

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-09 13:17:28 UTC
From: Terry Wagoner
Topic: 42650 Message: 42684

Mike: I knew you were building a dipole to use for the entire allotted band. Just wanted the newer folks to understand what you are telling them. You have to pick a frequency to apply 468/F to get your initial 1/2 wavelength physical wire length. Some folks like you will pick center of the band, some center of phone band, some center of CW band or some variation on these. Since I dont work near high end of phone bands but more commonly in the phone band I use frequency that is a little high of the center of the band.

However today what is being taught and partly due to solid state no tune finals is that you could never operate with such an antenna without a Tuner. The impedance excursions and resulting SWR would be too high.

For some folks that means once you move off resonance (which may be 1:3 to 1 if you are feeding a 65 ohm antenna with 50 ohm coax) you have to get that SWR down. I know folks who use Tuner with their resonant dipoles and trap beams and if they move off the resonant frequency 1khz they immediately re-tune the tuner. If that makes them happy no harm done.

You and I have both built many dipoles and inverted-V without a super wham-o-dyne analyzer. However, they are tools and like all tools can make job easier, more efficient, and faster. Additionally they can provide you with some data you would not otherwise get. The question is what do you use that data for? What does knowing your inverted-V feedpoint is 54.06 - J0.537 going to do for you? For average ham not much.

I think where the Analyzers really shine is in areas like tuning traps and building multiband antennas like an OCF. You can sweep the OCF and see where you have approx 200 ohms sweet spot to install your 4:1 balun. Without the analyzer have to use formulas and as many opinions as people. Do I cut from one end 33%,34%,or 38%? Takes lots of raising and lowering and trial cut and maybe add cycles. Not to mention lots of on-off heating cycles on your Hybrid finals.

I connected the analyzer directly to the dummy load, and impedance is 49.7 ohms. The SWR is 1:1 to 1.10:1 across the 20 m band.

My concern is that the rig does not behave like it normally does during tuning, and I am afraid that I have damaged my radio.

The fact that it has all taken place while I am experimenting with the length of my antenna, and analyzer actually is just a coincidence, because the rig behaves the same way when tuning into the dummy load.

Since testing the dummy load and finding it to be in good shape, it points more to the radio itself.

I just don't know what would make the rig behave this way, or what to do to correct it.

Some of these problems can be caused by heating of the antenna system (coax) components. You will not see these problems at the low power level of the analyzer but when you apply higher power from the transmitter you will get different results.

42687. KENWOOD HYBRID USER NET (June 9th, update)

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-09 18:44:27 UTC
From: mvgilger
Topic: 42687 Message: 42687

For next week, I will not be here to run the net. For the weekend of the 22nd, there will not be a net on Saturday, due to Field Day. Sunday should be ok as I think FD will have ended by the time the net starts.

The Saturday's net on 40 meter had 18 stations checking in with good band conditions. We had 7 new check-in's, W4OP, KK4JFP, W2UIS, KC2TFX, KC2TRX, and W2UDG.

Out of all stations checking in, there was:

2 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
2 running TS-830S
1 running TS-900S

I was running my TS-940s. The rest were running non hybrids of one model or another.

The Sunday's net on 20 meter we had 11 stations checking in under very poor band conditions. We had 5 new check-in, KB7DXN, N0RMB, W5JGV, KB7DXN, and KK6BQZ.

Out of those, there was:

1 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
2 running TS-830S

I was running my TS-940s. The rest were running non hybrids of one model or another.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39
April 2013, Saturday's net total = 52, Sunday's total = 29
May 2013, Saturday's net total = 45, Sunday's total = 50
June 2013, Saturday's net total = 19, Sunday's total = 20 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

Tom:

Are you saying that the Plate tuning capacitor now points to 21 mhz when loading on 20 meters into your dummy load instead of pointing at 14 mhz?

If so, I agree you should try a different coax jumper from rig to dummy load. If it still does it with another jumper then need to open rig and make sure the shaft coupler on the Plate Tuning capacitor isnt loose. You can tell by holding the capacitor shaft or plates and then turning the knob. If the knob turns the coupler is loose. Be careful so you dont damage any of the plates. I would full mesh them if going to hold them in place.

Terry K9TW

It will also tell you how broad band the dipole is and a conventional dipole is not very broad banded. It would not be unusual to have 1:2 to 1 at resonance (14.255mhz) and 2:1 at each end of the phone band. As Mike indicated many factors including apex height, nearby objects, apex angle, height of the ends etc. affect the SWR.

Yes Terry, that is it exactly. I intend to try a different coax jumper, and if I need to I will open the rig up.

I appreciate all of the patience, I suppose I am still apprehensive about the tuning procedure, and the damage I could do tuning.

I am trying to learn as much as I can though, and appreciate all of the advice.

Tom

> If so, I agree you should try a different coax jumper from rig to dummy load. If it still does it with another jumper then need to open rig and make sure the shaft coupler on the Plate Tuning capacitor isnt loose. You can tell by holding the capacitor shaft or plates and then turning the knob. If the knob turns the coupler is loose. Be careful so you dont damage any of the plates. I would full mesh them if going to hold them in place.

When I build a new antenna I always hang it up and run a charted sweep of the SWR vs freq on graph paper and refer to it for;
1. trimming it to the part of the band I operate on.
2. future reference, storm survival etc where I can see if anything has changed over time and can make an inspection to see what broke if the next sweep is way off from the original.
I HAVE GRAPHS PLOTTED IN A FOLDER IN MY DESK DRAWER FOR ALL MY ANTENNAS.

Terry,

I don't knowbut when I build and erect a dipole antenna, I don't use an analyzer. I use a simple SWR meter, some RF power applied to the antennafrom the transmitter (transmitter is tuned upinto a 50 ohm dummy loadfirst),
Cap to be pointing

Terry
I got the board removed today and found that the crystals were not
soldered very well from the factory.The rest of the board was fine,just
those two
Both Leeds were very lose and not much solder to hold them.Measurements
were fine.
I need to buy some better alignment tools and was wondering what you
might recommend
I have pasted this site as they have a nice assortment

http://www.mtechnologies.com/tools/index.htm#
<http://www.mtechnologies.com/tools/index.htm#alignset>alignset
<http://www.mtechnologies.com/tools/index.htm#alignset>

Thanks

42694. TS-530S VOX anomaly

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-10 01:44:14 UTC
From: Craig
Topic: 42694 Message: 42694

I have just a acquired a very nice TS-530S -- a real beaut. It has one problem -- and one only (and it may be me).

The anti-VOX seems to be non-functional. Any VOX gain setting above zero gets the VOX relay tripping repeatedly, no matter what anti-VOX adjustment is made, even if the speaker volume is low and the microphone (an MC-50) is remotely located. The VOX works normally with headphones muting the speaker.

Whaddya think?

Tom:

It is not likely you have done any damage to your radio although odd that there appears to have been some change. Did you use your rigs output to tune your inverted V prior to getting your antenna analyzer?

Multiple long key down cycles while trimming the antenna can be hard on it if not loaded properly and giving it a little rest.

Do you have an external wattmeter in line? Are you getting approx 100 watts output into dummy load and 20 meter inverted-V?

Here are some ways to hurt the radio (primarily shorten the life of your 6146 final tubes):

1. Long off resonance key down times (not having the plate current dipped to minimum) especially if tuning in CW mode instead of Tune mode. OK to tune in CW mode once you get some experience.

2. Routinely loading beyond recommended maximum Ip of 265 ma or tuning for Max Smoke and long key down at Max Smoke. Most of us who run TS-830s limit the plate current to approx 225ma for 100 watts output.

3. Running high duty cycle modes like PSK without reducing maximum plate current.

Contrary to popular opinion you will not burn up your 6146 tubes or arc over you loading capacitor if you load into an antenna that presents 2 to 1 VSWR. If you can load to approx 100 watt output at 225 ma it means that your pi-network was able to match the impedance that your feedline presented to it. It may not always result in the Plate tune and load controls pointing to where they do when you are loading into a 50 ohm resistive dummy load.

One additional question. Does your plate tune pointer now point to different place when you load on every band into your dummy load?

There are fixed padder capacitors that are switched in the plate tune and load capacitors and they can go bad, but not likely that all went bad at one time. None are switched in the Plate tune capacitor for 20 meters. They are switched in the Plate Load capacitor.

I would try another coax jumper between your rigs SO-239 connector and the dummy load (no antenna switch or any other devices in line) and see how the controls behave. If pointer remains out of alignment then it is time to inspect the Plate Tune capacitor coupling as I suggested.

Craig,

This is common when the vox delay hasn't been properly adjusted. You'll find this on the fron panel next to the send\rec paddle switch. It is most prob set to 0 or very low, turn to about 12 and see how you go from there. Once you know that is it you can set the delay to suit your needs if you use the VIX function.

Terry,

In relation to this problem with the misaligned plate cap, I asked Tom to check other bands, didn't receive any response back, if you recall that issue with the 830 we worked on where the 100,390 and 22pf caps on S22 were either out of spec or cracked, it wasn't aligned properly on all bands but still within marking referenc areas on front panel but not in normal postion. Would be a good reference spot to see if it is the PI circuit or just a change in resonance. Sorry to ask if I missed the respoinse. Starting to hear of a few more hybirds that are coming up with the S22 padder issue, simple fix really if it is that. Has there been any mention of a good earth on the radio?

Subject: [TS-520_820_530_830] Re: TS-530s Question

Tom:

It is not likely you have done any damage to your radio although odd that there appears to have been some change. Did you use your rigs output to tune your inverted V prior to getting your antenna analyzer?

Multiple long key down cycles while trimming the antenna can be hard on it if not loaded properly and giving it a little rest.

Do you have an external wattmeter in line? Are you getting approx 100 watts output into dummy load and 20 meter inverted-V?

Here are some ways to hurt the radio (primarily shorten the life of your 6146 final tubes):

1. Long off resonance key down times (not having the plate current dipped to minimum) especially if tuning in CW mode instead of Tune mode. OK to tune in CW mode once you get some experience.

2. Routinely loading beyond recommended maximum Ip of 265 ma or tuning for Max Smoke and long key down at Max Smoke. Most of us who run TS-830s limit the plate current to approx 225ma for 100 watts output.

3. Running high duty cycle modes like PSK without reducing maximum plate current.

Contrary to popular opinion you will not burn up your 6146 tubes or arc over you loading capacitor if you load into an antenna that presents 2 to 1 VSWR. If you can load to approx 100 watt output at 225 ma it means that your pi-network was able to match the impedance

that your feedline presented to it. It may not always result in the Plate tune and load controls pointing to where they do when you are loading into a 50 ohm resistive dummy load.

One additional question. Does your plate tune pointer now point to different place when you load on every band into your dummy load?

There are fixed padder capacitors that are switched in the plate tune and load capacitors and they can go bad, but not likely that all went bad at one time. None are switched in the Plate tune capacitor for 20 meters. They are switched in the Plate Load capacitor.

I would try another coax jumper between your rigs SO-239 connector and the dummy load (no antenna switch or any other devices in line) and see how the controls behave. If pointer remains out of alignment then it is time to inspect the Plate Tune capacitor coupling as I suggested.

If it still does it with another jumper then need to open rig and make sure the shaft coupler on the Plate Tuning capacitor isnt loose. You can tell by holding the capacitor shaft or plates and then turning the knob. If the knob turns the coupler is loose. Be careful so you dont damage any of the plates. I would full mesh them if going to hold them in place.

Don:

Very good. A lot cheaper than having to buy new xtal.

For years GC Electronics was the standard in alignment tools. I have a nice older set and have supplemented it over the years.

GC makes a 8 piece CB set and a 12 piece set you could consider for starters. Can find sets on Ebay from time to time and I think on Amazon.Com.

Hi Dave:

I agree he should check all bands and not just 20 meters. It is possible he is looking at a bad padder cap or bandswitch situation as you point out. Hopefully we can get the report back that we need to analyze the fault. Apparently was working ok and then after using rig to trim new 20 meter inverted-V the pointer on Plate tune cap no longer aligned as I understand the problem (both on antenna and dummy load).

I had also asked about what had happened to the Plate Load capacitor position and did not hear back. Suspect he is overloaded with responses and questions at this point.

I would much rather tighten the coupler than replace padder caps!

Don:

Very good. A lot cheaper than having to buy new xtal.

For years GC Electronics was the standard in alignment tools. I have a nice older set and have supplemented it over the years.

GC makes a 8 piece CB set and a 12 piece set you could consider for starters. Can find sets on Ebay from time to time and I think on Amazon.Com.

Thanks very much, Dave. Good idea but, unfortunately, that's not the problem this time. The VOX delay is set correctly. The VOX works fine, with a range of delays, if the speaker is muted, but with the volume up -- even to a point so low as to be inaudible -- the relaytrips repeatedly -- unless I unplug the mike.

Microphone cable wiring??

Craig,

Have you tried cleaning the pot with DeoXit F5 fader control cleaner
then rotate the pot throughout its travel several times?

I have just received pair of the HV electrolytics from K4EAA, so I was interested to notice that they also used wire wrap to those original electrolytics! Bit of a pain as I can't just desolder old leads and resolder - they are pretty tight do I will have to remove all the wiring associated with those caps and replace. It's strange as I used to do a lot of wire wrap in past but on logic boards, 5V not 500V!

Hi Terry,

Tighten the coupler so much easier and better, just thought I'd through my two cnets worth in just incase it was over looked. Would hate to see someone have to go through what we did for the 830s. Had a look at mine when I got home and remembered that my shaft coupler was loose aswell. Hopefully it isn't much but glad to help out if he needs to go through the padder issue. Hopefully we get to hear if the other bands are in or out of alignment.

Subject: [TS-520_820_530_830] Re: TS-530s Question

Hi Dave:

I agree he should check all bands and not just 20 meters. It is possible he is looking at a bad padder cap or bandswitch situation as you point out. Hopefully we can get the report back that we need to analyze the fault. Apparently was working ok and then after using rig to trim new 20 meter inverted-V the pointer on Plate tune cap no longer aligned as I understand the problem (both on antenna and dummy load).

I had also asked about what had happened to the Plate Load capacitor position and did not hear back. Suspect he is overloaded with responses and questions at this point.

I would much rather tighten the coupler than replace padder caps!

Craig,

Have you had a look at the anti vox on the rear panel? As Mike suggested good idea to give it a clean and lube with Deoxit. I had a Shure 444 that arrived with another radio and similar problem, ended up being a broken ground wire was shorting out and causing relay to trip

No need to wire wrap the leads of the new HV filter caps. Yes remove the old bleeder resistors and rf bypass caps. Take a picture or make a drawing of the as built wiring before you start removing the leads, jumper, and resistors/caps. Take note of the capacitor polarity.

When you unwind the leads you will have to cut off the curly ends and dispose as they will be brittle and work hardened. Will need to strip back and get new conductor to solder on the terminals. Control the cut ends so you dont have any wire clippings fall into the rig or fly into adjacent boards.

Lightly sand the terminals of Kens new filter caps and just make one or two wraps and solder the leads on. I use the bleeder resistor body to install the bypass caps across them and then use the resistor leads to shunt the assembly across the filter cap terminals.

If you end up with short jumper wire just make a new one with hook up wire and you should have enough B+ lead length and can usually pull up a little if needed.

If you have a LCR bridge and ESR meter good time to record the values of the new filter caps. Although likely for remaining life of the rig you wont have to worry about replacing them again. I record this stuff to aid me in future troubleshooting.

You can greatly improve your any old radio and give it a huge number of modern features using the free Ham created software HDSDR .

http://www.hdsdr.de/wnew.html

It takes a while to set it up and figure it out , but if your old Kenwood is your primary rig , its worth the effort.It gives you features like dsp noise reduction and variable dsp selectively that can be controlled while viewing the audio spectrum your listening to for example.For SSB LSB and USB you set the low and tune to 1 and the mode to USB.For cw you set the low to 1 and the tune to your favorite pitch .I used 850 hz .

Just to try it out , you just feed the audio form your radio to the line in of your computer and away you go . Later you can cut the coax going from the rx board to the input of the radios volume control and run the two lines to a male phone jack on the rear of the radio like I did .The low level sound form the rx board goes to the computers line in and the line out of the computer goes to the input of the volume control and then on to the audio power amp in the radio which totally integrates the software with your boat anchor . I even tried the software once on my 1950es Hallicrafter S-53 and the results were incredible .Later after getting a new KenwoodS TS-590 I returned the boat anchor to its original configuration .

I cleaned everything last night thanks to everybody's advice, and thanks for giving me the info so I could intelligently work on it!

I let it dry thoroughly and plugged it in later on last night. It seems to be as sensitive as before, and thankfully 14.000 and up the display is much more stable. 3.5 and up, not so much. Those digits fluctuate a good bit, especially when someone's signal is receiving very strongly.

Sounds like the leads should be resoldered. That I won't attempt since that's a pretty delicate situation, so I may find someone that is experienced enough to try that fix. Till then I'll keep on listening.

Taking my Tech test Saturday and really looking forward to it!

42710. VFO-820 - two sockets soldered together - can't work with the 9 pin cable

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-10 16:13:01 UTC
From: Barry
Topic: 42710 Message: 42710

I'm curious - I was cleaning the 820 last night and thought I'd try to connect the external VFO-820. I found the 9-pin cable the other day and tried to plug it into the VFO-820, but I saw when I unscrewed the cover of the plug-in socket that 2 sockets are apparently soldered together. The 2 soldered sockets are on the VFO-820 - not on the 820 itself.

I have read a couple of older posts that looked like the 820 itself used to have a couple of those pin sockets soldered together, but I'm not sure why this VFO-820 would have the sockets soldered together.

I have a picture here of the way it looks:

http://www.digcservices.com/ham/VFO-820BB.jpg

Is there a way I can get this VFO-820 to work?

Barry

That plug that is in the VFO is to be used on the back of the 820 if you have NO VFO attached.
Remove that plug, connect the cable from the radio to the VFO and all should be fine.
The 820 needs pins 8 & 9 jumpered on the back of the radio when no external VFO is used.

Barry,

  Gordon is right. I take it that the 820 you have is working correctly?? Is there a plug/jumper in 9 pin socket at back of the rig?
May I recommend that you take your DMM, or what ever you have, and check for continuity of the "remote vfo cable" If original,
one or more wires may have broken/come loose from one of the pins inside of the plug(s)
Having the jumpered plug in the back of
the remove vfo seems to be to serve no purpose...except possibly to keep it from getting lost

Yes, from what I can tell the 820 is working well and receiving a lot, actually. I heard from Canada to Pennsylvania last night and am keeping a log of all that I pick up on it just so I can go to some of the more frequented frequencies.

I'm going to check tonight when I get home to see how the external works - the actual cable looks like it ought to be okay, but the older remote cable is cracked all over. It's probably toast, but I know I don't need it for this external.

Craig,

This is common when the vox delay hasn't been properly adjusted. You'll find this on the fron panel next to the send\rec paddle switch. It is most prob set to 0 or very low, turn to about 12 and see how you go from there. Once you know that is it you can set the delay to suit your needs if you use the VIX function.

Subject: [TS-520_820_530_830] TS-530S VOX anomaly

I have just a acquired a very nice TS-530S -- a real beaut. It has one problem -- and one only (and it may be me).

The anti-VOX seems to be non-functional. Any VOX gain setting above zero gets the VOX relay tripping repeatedly, no matter what anti-VOX adjustment is made, even if the speaker volume is low and the microphone (an MC-50) is remotely located. The VOX works normally with headphones muting the speaker.

Whaddya think?

73,

Craig

John,
I think you should read up on the Softrock SDR and how it works.
I pick off some of the IF signal (from any older radio) and the Softrock SDR sends the info to the audio channels of the PC where the HDSDR displays the IF much like a spectrum analyizer.

Mike, So sorry for the long pause in the reply as I was on the road. I started back on the radio and I traced the plug wiring and found that the I get continuity between pins 3 and 5. I did turn off the sg switch. I did check this with the xmt/stby switch and even with the mike plugged in and still pins 3and 5 closed contacts. Could have someone have rewired the plug. Now I am wondering about the alc wiring. I did a complete recap and replaced the driver and finals and did the neutralization. The radio runs great but just will not run the amp.
Robert.

Are you trying to say there's some sort of frequency conversion going on
in a bit of hardware somewhere between the radio and the PC that
down-converts the 455kHz IF to something under the 20kHz that the PC
sound card can accept? Otherwise, shoving 455kHz into a circuit that
can handle AT MOST 23 or so kHz is going to cause some .... issues.

Some PC soundcards can handle 196KHz. I radio IF is fed to quaderature detector and that output is fed to the soundcard as the I/Q channels.

Try reading about "CWSKIMMER".

Wes, welcome to the world of SDR. That's what the softrock does - it's a
$25 SDR about the size of two fingers. RF in, AF (IQ format) out.

Robert,

I think you are mistakenly measuring continuity between pins "3" and "4" not pins "3" and "5".

Pin "3" on the rear 8 pin octal socket is connected to ground at relay terminals RL-4 in receive. In transmit, pin 3 is no longer connected to ground through relay terminal RL-4 BUT pin 5 "IS" connected to ground potential through relay RL-4. Have you looked at the 820 schematic's wiring of the rear 8 pin octal socket?

Pin 6, Remote ALC input, is connected to pin 7 "RLC" on the RF Unit's RF3 plug.

You should study the 820's schematic wiring so you will see how the socket's wiring should be. For amplifier relay control by the 820, including the remote ALC input, the only pins you should be concerned about are pins "5" and "4" for amplifier relay control and pins "6" and "4" for remote ALC input to the 820.

You said that you performed a "complete recap and replaced the driver and finals and did the neutralization". Did you replace "every" electrolytic capacitor in the 820? What troubleshooting results indicated you needed to do all those things?

I did study the schematics. It was on page 37 of the manual. I downloaded the manual, service manual, The red wire is on pin 3 and the l blue wire is on pin five and two disc caps are on pin 4. It shows pin 6 as alc input and pin 4 is ground.

I can send you pics. As far as the caps. All electrolytic caps were changed because the radio is over 25 years old and caps degrade over the years. Even new ones sitting on the shelves. They dry out. The finals were 6146As and weak and the driver tube, let's say there were fireworks in the tube when I tested it on my dyna-jet 707. Too much traveling I need to stay home more often.

Robert.

This really interests me! Any tips on getting the IF out off my TS-520? I saw the your mod for your TS-520s on your website. Are they the same?

I'm getting back into ham radio after a 30 year hiatus. I passed my tech last year, and taking General on Wednesday night. I purchased a TS-520 last year, but mostly have been listening. It seems to tune up ok into a dummy load, so I think it's in okay shape. I just order the re-cap kit from http://www.hybridrestore.com.

I have a degree in electronics, but haven't done any radio work, let alone transmitters, in a long time. I don't think the re-cap will be much of a problem.

Wish me luck with the re-cap project. Any suggestions are always appreciated.

Brett,

I don’t know what the input Z of the SM-220 is, but you would probably want to add a high-z buffer of some kind between this tap and the SDR to avoid potentially loading the IF.

There is plenty of drive available, and actually too much. I have to
throw in some 10-20db attenuation.
You want to pick off from the 8 Mhz IF, not 455, and Kenwood brings the
8Mhz out to the back panel on most models, even my TS940

42731. Need a 37.395 crystal for TS-520

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

Topic: 42731 Message: 42731

I a working on a TS-520 for a friend. He says "the 28.5 band doesn't work". On investigation I discover a CB mod. SOmeone installed a 36.395 crystal.

So I am looking for a 37.395. If some one has one to sell, please contact me off-list.

Thanks
Tim

I see ATX mentioned connecting to the volume control high terminal, that AIN'T I.F. it's AUDIO ! someone has the wrong info.

_____
From: Jan Servaites <jservaites@...>

John,
I think you should read up on the Softrock SDR and how it works.
I pick off some of the IF signal (from any older radio) and the Softrock SDR sends the info to the audio channels of the PC where the HDSDR displays the IF much like a spectrum analyizer.

Topic: 42600 Message: 42733

Robert,

Pins 5 and 4 on the 820's REMOTE socket should not have continuity in receive but should have continuity in transmit.

Pins 3 and 5 on the 820's REMOTE socket should have continuity in receive but should not have continuity in transmit.

Pin 6 (Remote ALC Input) on the 820's REMOTE socket and pin 7 "RLC" (Remote Level Control) on the RF Unit's RF3 plug should have continuity.

Pins 1 and 4 are ground (chassis).

Is it possible that a previous owner has changed the wiring on the 820's REMOTE socket? Yes anything is possible. You will have to use an ohm meter and the 820's schematic to determine what changes in the REMOTE socket's wiring, if any, exist then change the wiring to the REMOTE socket back to what it is suppose to be. I can't say why any previous owner would change the wiring on the 820's REMOTE socket. The relay terminals shown on the 820's schematic, "RL-1" through "RL-4" are the terminals on the relay located below the chassis inside the small metal enclosure between the final amplifier PC board and the rear panel.

I mean on disrespect but I would have never recommended replacing ALL of the electrolytic capacitors in the 820 at once simply because they are old. Replacing components in this manner is referred to as the "Shot gun" replacement method, a common method based on the misguided idea that, "the capacitors are old so they are probably bad or will go bad shortly so for insurance, I'll replace them all at once.". Using this method does not result in any improvement in overall performance but it can quite easily lead to additional problems such as cracked foil runs on the PC boards the 820 didn't initially have. The PC board foil runs are very thin and are easily damaged by heat and physical stress. A component, whether it's a capacitor, resistor, diode, or transistor of any type, should not be replaced unless there is physical evidence found during a visual inspection or results through troubleshooting circuits in the 820 that indicates the component(s) is/are bad.

Tim,

If no one has the 10 meter crystal you are looking for then I recommend International Crystals in Oklahoma City, OK They can make and sell you a replacement crystal for your 520 for about $22 plus a few dollars shipping. See their website at the link below.

http://www.icmfg.com/hamradio.html

They have an 800 number and they take all major credit cards. I have been dealing with them for years for all my crystal needs from Heterdyne crystals for my Drake B and C Line twins, Heathkit transmitter and transceiver HET OSC crystals to Regency scanner crystals (yep those old Regency scanners still work in many areas today). I use "Shara Gore" who works in sales.

I have never received a bad crystal from them and I've ordered plenty of crystals from International Crystals over the years. Their prices are the same as Jans Crystals in Ft Meyers, Florida who I have also dealt with in the past. If you are restoring the 520 then I would recommend new for the replacement crystal. You will have to perform the alignment once the replacement crystal is installed.

> Jan N8CBX
>

By setting the low freq to 1hz you are making the HDSDR work as a audio processor .The IF frequency is set up to be 1hz , and when in the usb position , you are hearing and processing audio frequencies and its being displayed from 1hz and up . What I could see on the spectrum display was only from 0hz to 4khz the way I had it set up .

I might point out that I had to use a IF , or low freq , of 1hz instead of 0 hz because I had problems with the software not recognizing 0 hz.

I set the input sampling rate on the HDSDR at 10.025k and the output rate at 8k . On my TS-530s the audio came out of the 1st audio amp after the detector which was an ideal level for feeding the line input to the computer sound card . The audio is then processed using HDSDR and sent out of the line output and on to the TS-530S volume control and then on to the 530's audio power amplifier IC .

This idea of using HDSDR with my radio is similar to what I did in the 1970es as a kid with a AUTEK analogue type audio filter used on my Hallicrafter FPM-300 transceiver that only had a 2.1khz ssb filter .With this set up I liked the fact that once I got all the input/output audio levels correct I could adjust the sound using the rigs volume control and in effect the audio processor became just another stage in the radio.

I found from using this set up that its to bad that modern radios no longer use a RF type IF shift like the older radios do .The combination of a RF IF shift with a a 500hz roofing filter feeding a narrow but ring free dsp audio filter is a very effective combination and gives the user I think the best of the analogue and digital worlds.

note :Copy and paste this url to see a crude picture of what I did .

http://s237.photobucket.com/user/rtaylor0361/media/a3064338-812e-4694-9ab4-adef190fb66d_zps6a47bde1.jpg.html

When the audio levels were properly set ,the audio quality using my sound blaster card was excellent and found no reason to set up a way to add a bypass switch to the HDSDR stage I had added to my radio.

Topic: 42708 Message: 42736

I might also point out that during the time that I was using HDSDR with my TS530S , I noticed that adjusting my radio to the desired signal using both my ear and the HDSDR used as a audio spectrum analyzer was a better and more effective way to tune your radio so today I am using the HDSDR with its dsp filtering funtions off just to view the audio spectrum from 1hz to 4khz as I tune my TS-590S to the desired signal and adjust its DSP filters.

42737. Is your boat anchor acting like a room air filter ?

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)

From: wa4axt
Topic: 42737 Message: 42737

In the 70es I had a Hallicrafter radio that had a fan attached to it to cool the sweep tube finials .After a few years of use I started having intermittent problems that appeared to be related to the units various switches and the radios uncovered tx/rx change over relay . After opening the radio it was obvious that the cooling fan was sucking air and dirt into the radio cabinet and dirt was accumulating everywhere . I blew out the dirt and cleaned the switches and all was fine. To prevent this problem in the future , I cut strips of filter material from a home AC filter and using duct tape created a crude filter for my radio. I also covered the adjustment holes with scotch tape . This arrangement was by no means air tight but did the job very effectively .In 2007 when I got my TS-530S ,I blew out the large amount of accumulated dirt that was in it using a leaf blower (lol),and after adding the filters the radio inside has been clean of dirt ever since.

A recent look at the trouble shooting guide of my TS-590s said that if one is experiencing low transmit output , it could be due to a dirty cooling fan filter . I was sure glad that Kenwood , unlike other radio builders , finial recognized this problem and took action to prevent dirt build up in the radio .
You may want to consider installing air filters on any boat anchor you might have that uses a cooling fan.

I was able to plug it in last night and get it powered up. What are the optimum settings for using the external VFO? I didn't hear much coming from it when I tried it, but I may not have had it set right.

The cable fit just fine once I pulled the jumpered pins out of the external VFO.

Barry:

There are no optimal settings just how you chose to operate. The external or remote VFO allows you to run split operation to chase DX. Most folks leave the rig VFO on TX and the remote on RX. You can use whatever combination you want.

I recommend a remote VFO for several reasons;
1. You can even out or distribute the mechanical wear of the drive train. Often the internal VFO has had thousands of lock to lock operations and will have excessive axial and radial wear. Remote VFOs typically have far fewer operations on them and less wear so wont have a VFO knob that looks like it is on an eccentric.

2. Of course you get the operational flexibility that it allows. TX/RX on internal. TX on internal and RX on Remote, TX on Remote and RX on internal, and RX/TX on Remote.

3. Troubleshooting: If the internal VFO has excessive drift after warm up then switch to the remote VFO and see if you have same excessive drift. If you do then the most likely cause is bad regulated 9vdc. If you do not then problem is likely internal to the rigs VFO.

I have two TS-830s each with a VFO-240 and I would not be without them.

You are making me a little nervous, but start by going to the AF-AVR board and measuring the 14vdc input and 9 vdc regulated output and the RF-1 3.3vdc output.

Anytime you are replacing boards do not plug or unplug Molex connectors with the rig powered on.

When making energized measurements use a jumper lead to connect the negative lead of your measuring device to chassis ground. This way only have to control the positive test prod. Make sure you are aware of where your other hand and body is at relative to the chassis.

For high voltages I would consider powering down the rig and use jumper leads to connect both test leads and then power on and take the reading and then power down to remove both test leads. Make sure you have good test leads (no frayed or cracked insulation, and/or wire ends exposed at the clips or prods). Make sure you make good positive mechanical connections so the clip leads cannot pop off and fly into the energized rig.

You must be aware of the voltages in this radio and where you can get in trouble if you make accidental hand contact or have a lead or some other conductor drop into the radio. It takes understanding of where the hazards are at in the radio and how to safely manage those hazards by employing good safe work practices. Attention to detail is a must.

Not scolding you just dont want to see you get hurt.

One hand on the probe, the other in your back pocket.

That's how I was taught to handle high voltages. You learn QUICKLY when troubleshooting an old television (what I learned on, tube tv's and am radios) if you slip taking a high-voltage reading off a TV fly-back transformer and it bites you.

Saw a classmate go nearly 20 feet from the muscle-spasm.

B-Plus is nothing to mess with if you're tired, inattentive, worried, or otherwise distracted. Make sure others around you know that for whatever short time (and tell them when you're done) you're too busy with something dangerous, please no distractions.

If you find yourself trying to contort and wiggle around to get the probe in place, STOP! and work out another way. Maybe a clip lead when it's powered down, or even a quick tack-job with some wire and a soldering iron. (Don't see that being needed in these rigs so much as some older gear.) If you can't reach it without being a double-jointed chimpanzee, something isn't right and you're very likely to slip and cause a serious short somewhere. Been here. Done this. It got expensive, and quick.

And DON'T do this kind of thing in an otherwise-empty house! Make sure someone is around the place and looks in on you occasionally. Invite a friend or neighbour over if you have to. It might mean the difference in surviving a zap and not. Time is CRITICAL if you take a high amperage surge across the chest cavity and stop your heart.

If you're not used to big values of voltage and amperage, stay out of the chassis and get help. Hams are all over the place, and a lot of them and in particular those of us aulde phartes who grew up with this stuff already know the tricks. Terry has given several good ones.

Be safe, I get club notices of "Silent Keys" nearly every week from the local groups. Don't need more unnecessary ones from here, thanks anyway.

This is another reason to learn basic electricity and electronics! don't mean to sound disrespectful but there are too many hams today that think they know but in reality they don't. Also, it has been said many times, there are voltages inside the hybrids that can easily KILL YOU if you do not use proper safety precautions and do not respect the AC and DC voltage that exist inside the hybrids! Some may think we are talking down to them or being disrespectful but that is not true!! There are too many hams and people in general who are now SK's because they didn't follow safety precuations, didn't pay attention, and/or were distracted by something while they were working around AC or DC voltages! Remember, it's not the voltage so much that does the damage but rather the "current"! A recent news spot talked about a man who was in a lift bucket that was killed when his head came in contact with "80KV". I suspect when the investigation is over, it will be found that he was "distracted" or "wasn't paying attention"! We all have made those mistakes, not paying attention, been distracted, etc., so we know what happens so don't take it personally, we are only telling you these thing so you won't make those mistakes!

Hi Group This is my first post. I recently purchased a near mint 820S for under $300 shipped with CW filter. WOW beautiful condition electrically and physically......I would rate it a 9.7/10. It also has a KB1 VFO knob.
One minor problem....the VFO calibration ring sometimes gets tight when turning the VFO hence the VFO calibration can shift. Is the VFO ring to tight against face plate body??

Now if I could find a 830S in the same condition I would find nirvana.

Bill,

I think that maybe the KB1 knob is a little to close to the face plate. Grab the VFO knob...wiggle it up & down....any play? Pull...in and out (gently)..any play?
My guess is no, to both questions. Many times after getting a rig that has been shipped by...well...I won't name them......

Obtain... a 1.5mm allen wrench...loosen the "set screws" of the KB1 knob...and remove...using your fingers...rotate the VFO shaft and check for
any rough spots/binding through its entire travel...several times....I will guess that it will be fine...reinstall the KB1 and adjust the clearance between it...dial skirt..face plate.....there should be a spring and two washers....washer...
spring...washer..skirt/knob...etc for smooth operation...even a 0.5mm 'bit extra clearance will make it fine..with no effect to operation

I think I gave you a good first place to look but I can see you have apparently dismissed that.

Funny how leads can short to ground when the rig is down powered and unplugged! Good luck.

To All,

Many test probes have a lot of metal tip exposed which is just begging to contact something other than the small point you want to measure. Years ago I covered a couple of my probe set tips with heat shrink tubing (when I graduated from electrical tape!) right to the points leaving no more than approximately 1mm exposed. That significantly reduces the chance of shorting to an adjacent component, ground, etc. It also reduces the damage done if the probe slips off the point you are measuring. I have other probes that can be used when I need to attach an alligator clip as well as dedicated leads with alligator clips and banana plugs.

The link below shows relatively inexpensive insulated test probe 2" (50.8mm) extensions that slip onto your probes and work very well for making measurements in a crowded chassis:
http://www.amazon.com/Fluke-TP88-Rigid-Probe-Length/dp/B000VRFL10

A more expensive probe option is the adjustable/retractable length, from 0 to 76 mm (almost 3"), insulated probes found at the following site:
http://www.fluke.com/fluke/usen
/accessories/test-leads-probes-and-clips/tl40.htm?PID=56751

What in the heck is happening here recently. What kind of Hams do we have as members now?

No one called you a dumb ass or idiot or stupid. No one held you up to ridicule or made an example out of you. You came here and said a "burned out resistor lead shorted to chassis while you were troubleshooting" and now want to know where to look. Well what the heck is a burned out resistor lead and how did it contact the chassis?

No one knows anything about your knowledge or experience level so anyone with an ounce of brain would be concerned about giving you any unqualified direction where to put your fingers next into a box full of rattle snakes.

You call coaching on risks and risk management being FLAMED. That is insane. You would not have made it in Fossil or Nuclear Power electric shop for 10 minutes if you are that thin skinned. I will never assume you know anything or have any experience level and even if your were a Senior Tech with 30 years experience you would get a pre-job briefing that would include the hazards associated with the job and the required PPE and safe work practices. I would be derelict in my duties if I just assumed you knew and understood.

If you call this being Flamed then I feel sorry for you. I can put my head on the pillow tonite.

Terry K9TW

Sometimes it is not the shock but the cuts that result from "flying" back. Those TV cage edges were razor sharp. The numb elbow and hand is bad but the dripping blood is not any fun. I am not proud to acknowledge how I know about that.

I sometimes wonder why I am still alive today! My career lasted around 45 years, working with both high voltage and high current electronic systems. In spite of all that experience, I felt the "bite" of a flyback transformer, and the sour taste of RF in the fillings of my teeth at least once in my life. I have also had hot solder drip onto my hand, and can still show you the scar that resulted from that instance!

I agree with all the voices of experience that are admonishing the OP about his "troubleshooting skills". I have no pity for anyone who believes they know enough to badmouth a group of experienced guys, and decides that he will do better by going it on his own.

I was going to post a much harsher E-Mail than any of the other fellows did, but they beat me to the punch with much more gentle words. Now I am glad that the OP didn't turn around and kick me in the head for something I might have said !

Jim AG3Y - Retired Chief Engineer Stereo FM station, Assistant CE UHF Television station, Technical Specialist Satellite R&D Lab, etc.

Ah hell...you guys have never experienced REAL voltage! You don't have to worry about blood.... the high voltage cauterizes the wound! LOL I got hit diagnosing weird power outputs on a Henry 2KD. My voltage probe wasn't quite long enough and as I was probing a 500 volt circuit, I grounded my wrist as the top of my forefinger touched a voltage bridge. All I gotta say is, sure glad I follow the 'one hand behind me' rule, when I am fooling around with high voltage! My whole right arm was numb for 2 hours afterwards...no blood though....the burn sure was deep...took almost 2 months to heal/

(Terry, you are right though...I didn't have a high voltage cage to worry about...I had already removed all of that. (Although, the cat took over 2 weeks to forgive me for elbowing her across the room from the 'fly back'.) <<GRIN>>

Joe - W7RKN

42756. Curious about what can be done with the TS-820 when connected to a Mac/PC

Yahoo group: TS-520_820_530_830 (2013-01 — 2013-07)
Date: 2013-06-11 18:47:18 UTC
From: Barry
Topic: 42756 Message: 42756

I'm investigating what can be done when connected to a PC with my TS-820. I know the newer radios have data cables, etc. that can be connected, but what can I enjoy with the 820? Very remedial question, I know, but I can tell you guys know your stuff and can point me in the right direction.

I even have the first PowerMac 6100 that I bought in 1995. I paid $6500 for it and for the Adobe graphics programs that I needed to get up and going in Graphic Design, and rather than sell it for $20 I've just kept it at home.

I'd connect it if feasible just to have something to decode Morse code and anything else I can do with it, but I'll hook up a new(er) computer to get more features. Just curious to see what you guys think. Thanks,

Barry

Bill, I have a niece that is always on Facebook preaching about the way drivers are be rude and dangerous to bike riders, the message is true enough but after a while it just gets really old. Some on this board are just religious about safety, true enough, but it does get old. So just kick back, take the really good info and let the rest slip by. Live long and prosper :)

Terry: There are two kinds of people who have worked with high voltages in things like TV and radio and Ham gear. (Not talking about transmission line power workers here, just gear-head techs like us.)

One type admits that they've gotten a case of the stupids for that split second needed to learn just what it feels like. (Some of us could still spit sparks, and 110VAC is just a minor sting these days...)

The other type are called "LIARS." <-;

As in around fifteen clams.

Now if I can only get there (a hundred or so mile trip) before someone beats me to it....

Needs test leads, of course. Also likely needs a couple of tubes, a lot of DeOxit, and some capacitors and such. But it is mainly just neglected, it seems.

Trying to make the trip on Friday, wish me luck.

There are PC programs for decoding CW and the digital modes(RTTY, etc).

You connect the speaker output 820 to the line in jack of your PC. No mods to the radio.

But it best if you use audio isolation transformers between the radio and the computer.

just to relate a little story/ i was a ships service electricion(sp?) in the navy and was very instilled in us to power down open breakes etc/I was working on a hi pressure air compressor/water cooled 440 three phase / just changing a leaky cooling solinoid turned off and tagged the breakers etc/ cut thru a lead with my tl-29 pocket knife/ and a half second later the tl-29 waas stuck in a steel bulkhead from my contortion when that third phase to ground thru my body in saltwater on the deck/knocked me silly/ I had tripped and tagged the wrong breaker and tho i checked between the leads and it was down it was still hot to ground/ so mistakes happen and it can cost u ure life i was dang lucky it didnt kill me

  and i certainly agree with being safe and noone here knoiws how much i know about electronic or eletricity /these people wont tell u to do something that can kill u without warning of the dangers because they want to know they didnt cause ure early demise/dont take it personal i shure wudnt! just my 2 cents / this is a great group of guys with lots of knowlage

What in the heck is happening here recently. What kind of Hams do we have as members now?

No one called you a dumb ass or idiot or stupid. No one held you up to ridicule or made an example out of you. You came here and said a "burned out resistor lead shorted to chassis while you were troubleshooting" and now want to know where to look. Well what the heck is a burned out resistor lead and how did it contact the chassis?

No one knows anything about your knowledge or experience level so anyone with an ounce of brain would be concerned about giving you any unqualified direction where to put your fingers next into a box full of rattle snakes.

You call coaching on risks and risk management being FLAMED. That is insane. You would not have made it in Fossil or Nuclear Power electric shop for 10 minutes if you are that thin skinned. I will never assume you know anything or have any experience level and even if your were a Senior Tech with 30 years experience you would get a pre-job briefing that would include the hazards associated with the job and the required PPE and safe work practices. I would be derelict in my duties if I just assumed you knew and understood.

If you call this being Flamed then I feel sorry for you. I can put my head on the pillow tonite.

Terry: There are two kinds of people who have worked with high voltages
in things like TV and radio and Ham gear. (Not talking about
transmission line power workers here, just gear-head techs like us.)

One type admits that they've gotten a case of the stupids for that split
second needed to learn just what it feels like. (Some of us could still
spit sparks, and 110VAC is just a minor sting these days...)

The other type are called "LIARS." <-;

Subject: [TS-520_820_530_830] Curious about what can be done with the TS-820 when connected to a Mac/PC

I'm investigating what can be done when connected to a PC with my TS-820. I know the newer radios have data cables, etc. that can be connected, but what can I enjoy with the 820? Very remedial question, I know, but I can tell you guys know your stuff and can point me in the right direction.

I even have the first PowerMac 6100 that I bought in 1995. I paid $6500 for it and for the Adobe graphics programs that I needed to get up and going in Graphic Design, and rather than sell it for $20 I've just kept it at home.

I'd connect it if feasible just to have something to decode Morse code and anything else I can do with it, but I'll hook up a new(er) computer to get more features. Just curious to see what you guys think. Thanks,

Barry

I use the phone patch all the time for PSK31. I just run straight cables from the computer to the radio. I use fldigi for the software. The only tricky part is the stability of the VFO, I'm considering buying a crystal for the PSK frequency to lock it down.
